Lecture 5: Intermediate macroeconomics, spring 2016

Lars Calmfors

Literature: ***Krugman–Obstfeld–Melitz, chapters 16 and 17.***

Stockholm University

Topics

- **Absolute and relative purchasing power parity (PPP)**
- **The Balassa-Samuelson effect**
- **The monetary approach to the exchange rate**
- **The Fisher effect**
- **The real exchange rate**
- **The relationship between the real exchange rate and the current account**
- **The Marshall-Lerner condition and the J-curve**
- **Short-run equilibrium in a small open economy with a flexible exchange rate (the AA-DD model)**
- **Stabilisation policy in the AA-DD model**

Stockholm University

Purchasing Power parity (PPP)

- **Theory of long-run exchange rate determination**
- **Focus on the importance of goods markets (as opposed to asset markets)**
- **Developed by Swedish economist Gustaf Cassel (1866-1945) in 1920**

Law of one price for a single good *i*

$$P_{US}^{i} = E_{\$/€} \times P_{E}^{i}$$

$$E_{\$/€} = P_{US}^{i} / P_{E}^{i}$$

Absolute PPP

$$E_{\$/€} = P_{US} / P_{E}$$

Relative PPP

$$\frac{E_{\$/€,t} - E_{\$/€,t-1}}{E_{\$/€,t-1}} = \pi_{US,t} - \pi_{E,t}$$

$$\pi_t = (P_t - P_{t-1}) / P_{t-1}$$

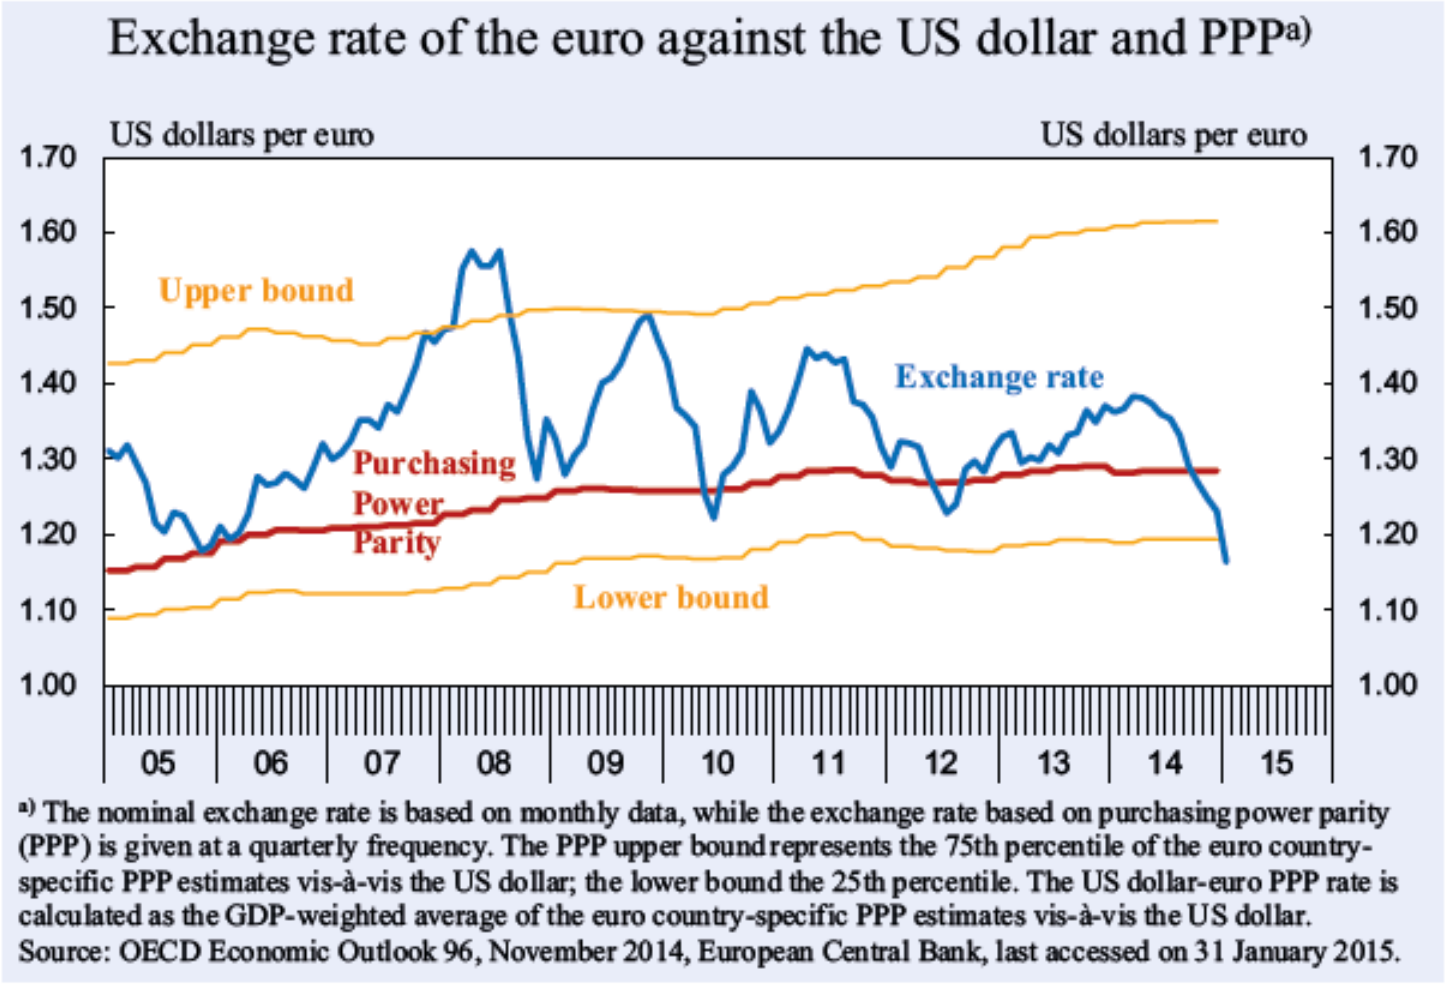
Figure 1.24 EEAG report 2015



[a)] The nominal exchange rate is based on monthly data, while the exchange rate based on purchasing power parity (PPP) is given at a quarterly frequency. The PPP upper bound represents the 75th percentile of the euro country-specific PPP estimates vis-à-vis the US dollar; the lower bound the 25th percentile. The US dollar-euro PPP rate is calculated as the GDP-weighted average of the euro country-specific PPP estimates vis-à-vis the US dollar.

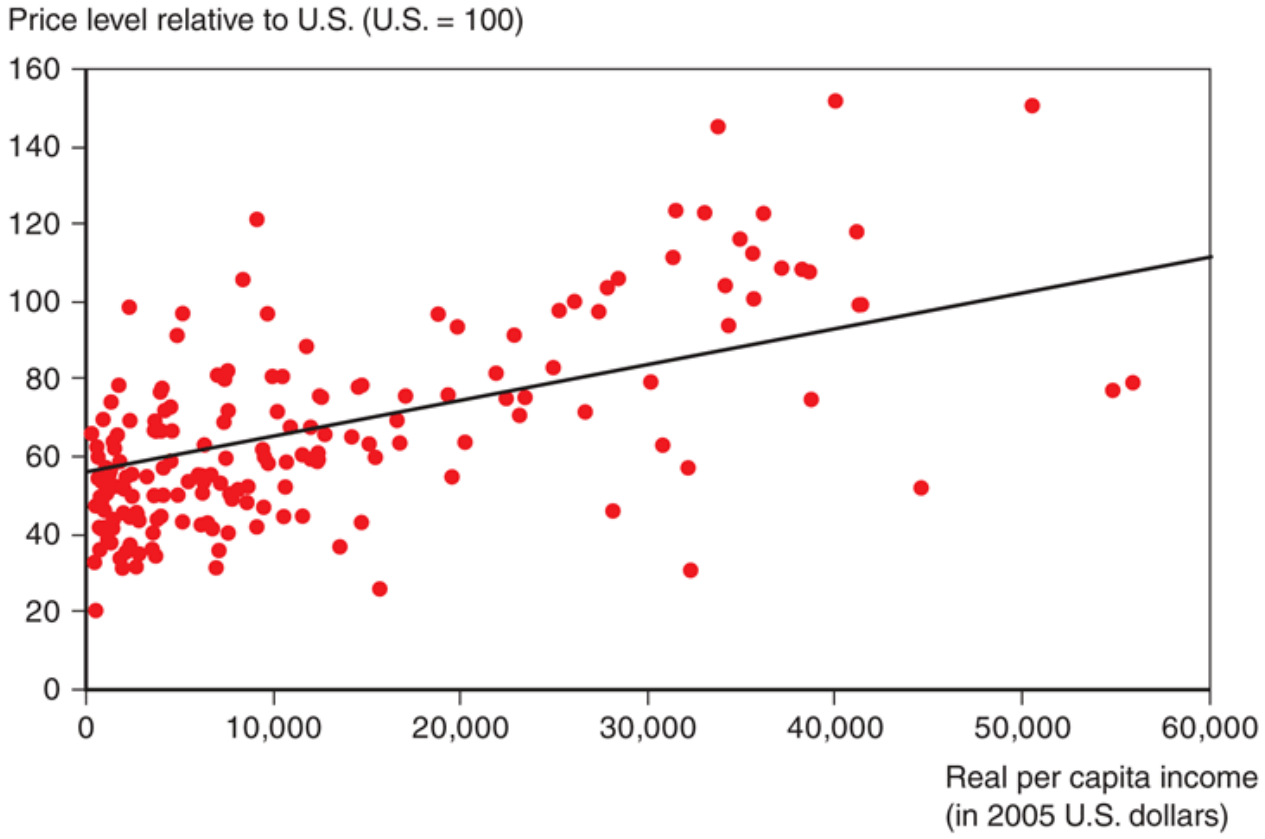
Fig. 16-3: Price Levels and Real Incomes, 2010



Source: Penn World Table, version 7.1.

Causes of deviations from PPP

1. **Transport costs and trade barriers**
2. **Differences in consumption baskets**
3. **Imperfect competition – price discrimination - pricing to market**

Different types of goods and services

- **Tradables or traded goods**
- **Non-tradables or non-traded goods (primarily services and building)**

The Balassa-Samuelson effect

The price level is higher in countries with high per capita income, because prices of non-tradables are higher.

(1) $P_T = EP_T^*$ (international goods arbitrage)

(2) $W_T = P_T \cdot MPL_T$ (profit maximization in tradables sector)

(3) $W_N = W_T$ (homogeneous labor market)

(4) $P_N = W_N / MPL_N$ (price = marginal cost for non-tradables)

(5) $P_C = P_T^{\propto} P_N^{1-\propto}$ (consumer price index)

The Balassa-Samuelson effect implies a higher relative price for non-tradables in rich than in poor countries:

Substitutions from the above equations imply:

$$\frac{P_N}{P_T} = \frac{1}{P_T} \cdot \frac{W_N}{MPL_N} = \frac{1}{P_T} \cdot \frac{W_T}{MPL_N} = \frac{P_T \cdot MPL_T}{P_T \cdot MPL_N} = \frac{MPL_T}{MPL_N}$$

$$\frac{MPL_T}{MPL_N} \uparrow \Rightarrow \frac{P_N}{P_T} \uparrow$$

The Balassa-Samuelson effect cont.

- **Compare countries with the same currency (for example countries in the euro area)**
- **P_T is the same everywhere because of goods arbitrage**
- **MPL_T is higher in rich than in poor countries (more real and human capital gives higher productivity).**
- **Higher MPL_T implies higher $W_T = P_T \cdot MPL_T$.**
- **A homogenous labour market implies $W_N = W_T$**
- **Differences in MPL_N (the marginal product of labour in the non-tradables sector) between countries are small (a hair cut takes more or less the same time everywhere)**
- **Because $P_N = W_N / MPL_N$, the price level for non-tradables must be higher in rich than in poor countries**
- **Hence P_C (CPI) must be higher.**

The monetary approach to the exchange rate

$$E = P_{US} / P_E$$

$$P_{US} = M^S_{US} / L\,(R_{\$}, Y_{US})$$

$$P_E = M^S_E / L\,(R_{€}, Y_E)$$

The fundamental exchange rate equation

$$E = P_{US}/P_E = (M^S_{US}/M^S_E) \times [L(R_{€}, Y_E)/L(R_{\$}, Y_{US})]$$

An increase in money supply in the US relative to Europe ($M^S_{US} / M^S_E \uparrow$) causes a nominal depreciation of the dollar ($E\uparrow$).

Stockholm University

The Fisher effect

(1) $R_{\$} = R_{€} + (E^e - E)/E$ **(Interest rate parity)**

(2) $\frac{E^e - E}{E} = \pi^e_{US} - \pi^e_E$ **(Relative PPP)**

Substitution of (2) into (1) gives:

$R_{\$} - R_{€} = \pi^e_{US} - \pi^e_E$

The Fisher effect: a 1 percentage point rise in inflation in one country causes a 1 percentage point increase in the nominal interest rate.

Figure 5-3: Inflation and nominal interest rates over time in Sweden

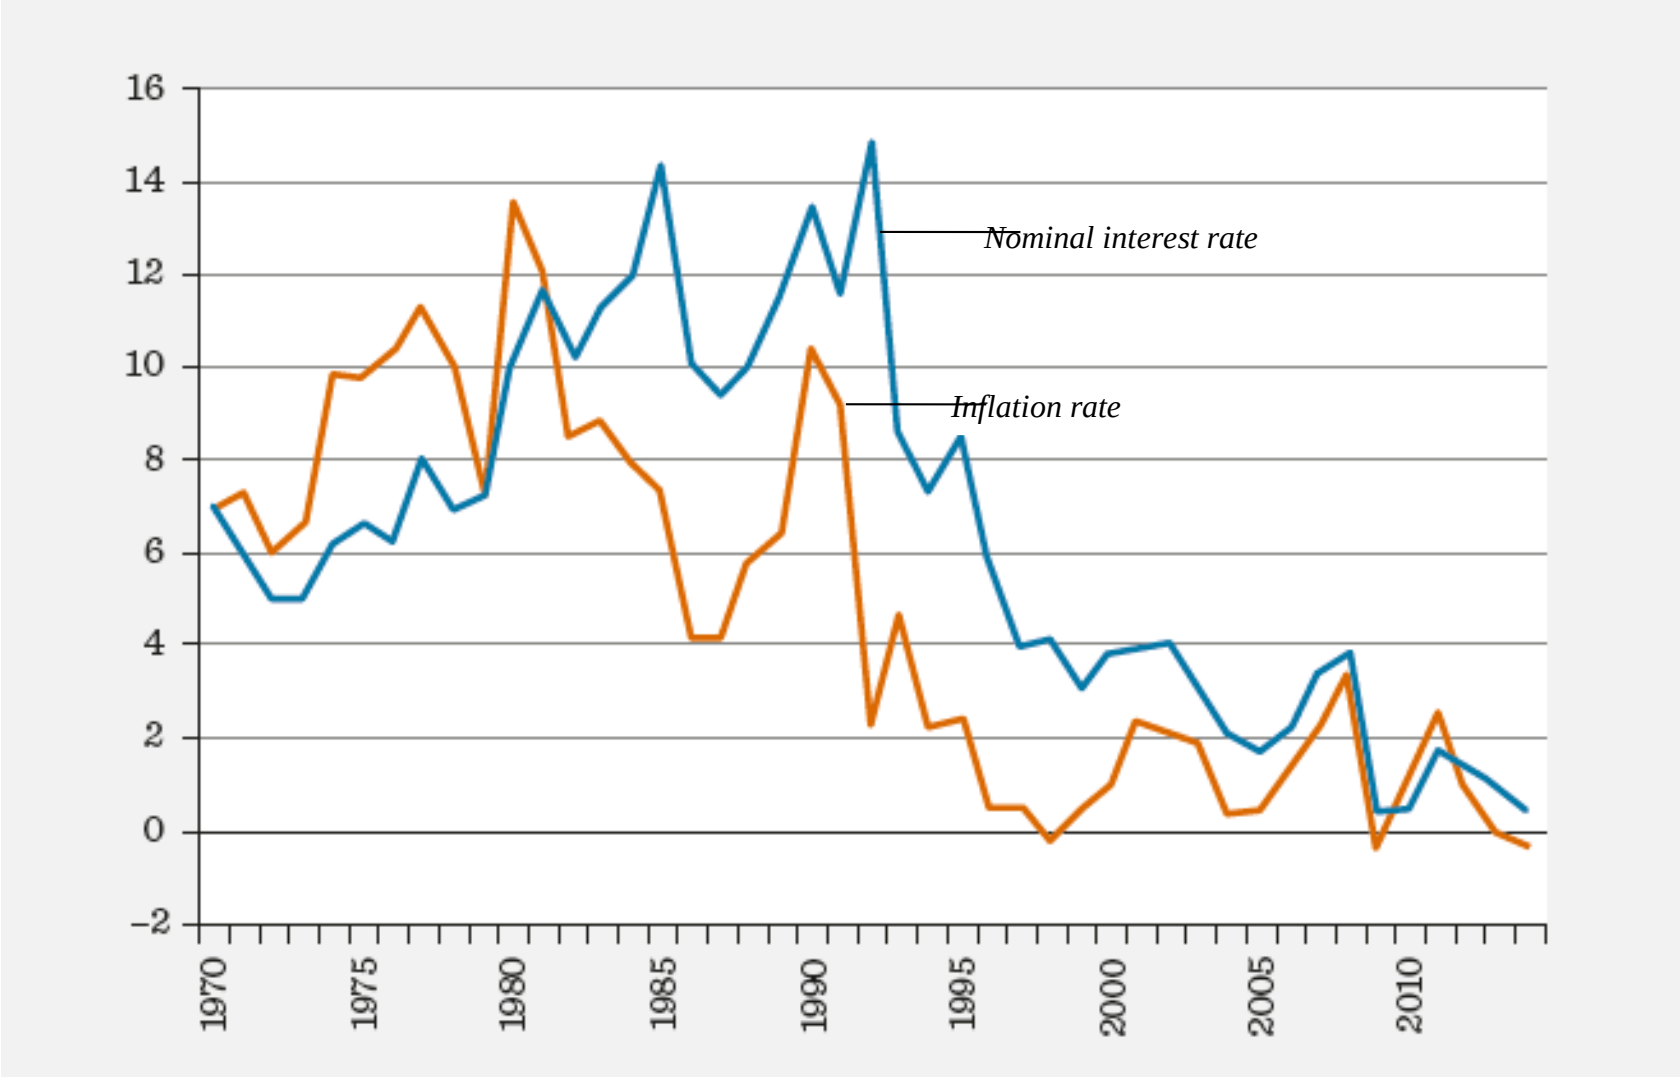


Figure 5-4: Inflation and nominal interest rates across countries

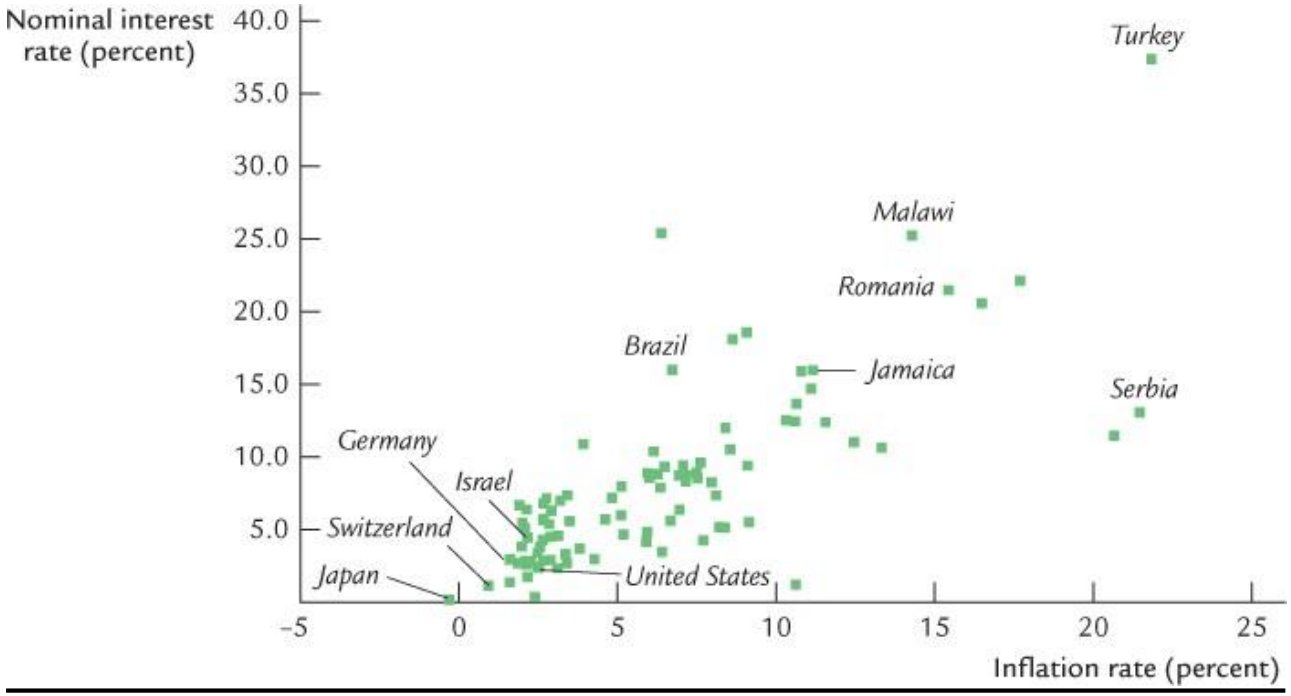

Interest rate differentials and real exchange rate changes

Definition of real exchange rate: $q = EP_E / P_{US}$

Expected real exchange rate change: $\frac{q^e - q}{q} = \frac{(E^e - E)}{E} + \pi_E^e - \pi_{US}^e$

Interest rate parity: $(E^e - E) / E = R_\$ - R$

Substitution implies: $\frac{q^e - q}{q} = (R_\$ - R_€) + \pi_E^e - \pi_{US}^e$

$$R_\$ - R_€ = \pi_{US}^e - \pi_E^e + \frac{q^e - q}{q}$$

Nominal interest rate differential = inflation differential + real depreciation

$$(R_\$ - \pi_{US}^e) - (R_€ - \pi_E^e) = \frac{q^e - q}{q}$$

$$r_{US}^e - r_E^e = \frac{q^e - q}{q}$$

r **= real interest rate**

Real interest rate differential = real depreciation (this is called real interest rate parity)

A short-run general equilibrium model for an open economy with a flexible exchange rate

Aggregate demand for domestically produced goods

$D = C + G + I + CA$

$C = C(Y - T)$	**Consumption function**
$G = \overline{G}$	**Exogenous government expenditure**
$T = \overline{T}$	**Exogenous lump-sum tax**
$I = \overline{I}$	**Exogenous investment**

$CA = EX - IM = EX - qIM^*$

$q = \frac{EP^*}{P}$ = **the real exchange rate**

The current account (net exports) should be measured in terms of the same numéraire (here domestic goods). So *IM* is imports measured in terms of domestic goods. *IM is imports measured in terms of foreign goods.**

$EX = EX(q, Y^*)$

$IM^* = IM^*(q, Y - T)$

$CA = EX(q, Y^*) - qIM^*(q, Y - T) = CA(q, Y^*, Y - T)$

A real depreciation ($q\uparrow$) need not improve the current account ($CA\uparrow$). Volume effects on exports and imports work in this direction, but the value effect on imports works in the reverse direction.

Marshall-Lerner condition

A real depreciation will increase net exports if the Marshall-Lerner condition holds.

The price elasticity of exports + the price elasticity of imports > 1

Then the volume effects dominate the value effect for imports.

All elasticities are defined to be positive.

Mathematical derivation of Marshall-Lerner condition

$$CA(q,\ Y^*,\ Y-T)\ =\ EX\,(q,\ Y^*)\ -\ qIM^*(q,\ Y-T)$$

Wanted: a condition for when $\frac{dCA}{dq} > 0$

Recall the rule of differentiation for a product

$$\frac{d[v(x)u(x)]}{dx} = v_x(x)u(x) + u_x(x)v(x)$$

This implies that $\frac{d\{qIM^*(q,Y-T)\}}{dq} = IM^*(q,Y-T) + qIM_q^*(q,Y-T)$

Hence: $$\frac{dCA}{dq}\ =\ EX_q\ -\ IM^*\ -\ qIM_q^*$$

Multiply the equation by *q/EX*.

$$\frac{q}{EX} \times \frac{dCA}{dq} = \frac{qEX_q}{EX} - \frac{q^2IM_q^*}{EX} - \frac{qIM^*}{EX}$$

Assume that *CA* = 0 initially, so that *EX* = *qIM*=IM*. Then:

$$\frac{q}{EX} \times \frac{dCA}{dq} = \frac{qEX_q}{EX} - \frac{qIM_q^*}{IM^*} - 1$$

$$\frac{dCA}{dq} > 0 \Leftrightarrow \frac{qEX_q}{EX} - \frac{qIM_q^*}{IM^*} > 1$$

$$\frac{qEX_q}{EX} = \frac{q}{EX} \times \frac{\partial EX}{\partial q} = \eta = \textbf{price elasticity of exports}$$

$$-\frac{qIM_q^*}{IM^*} = -\frac{q}{IM^*} \times \frac{\partial IM^*}{\partial q} = \eta^* = \textbf{price elasticity of imports}$$

All price elasticities have been defined so that they are positive.

$$\therefore \eta + \eta^* > 1 \Rightarrow \frac{dCA}{dq} > 0$$

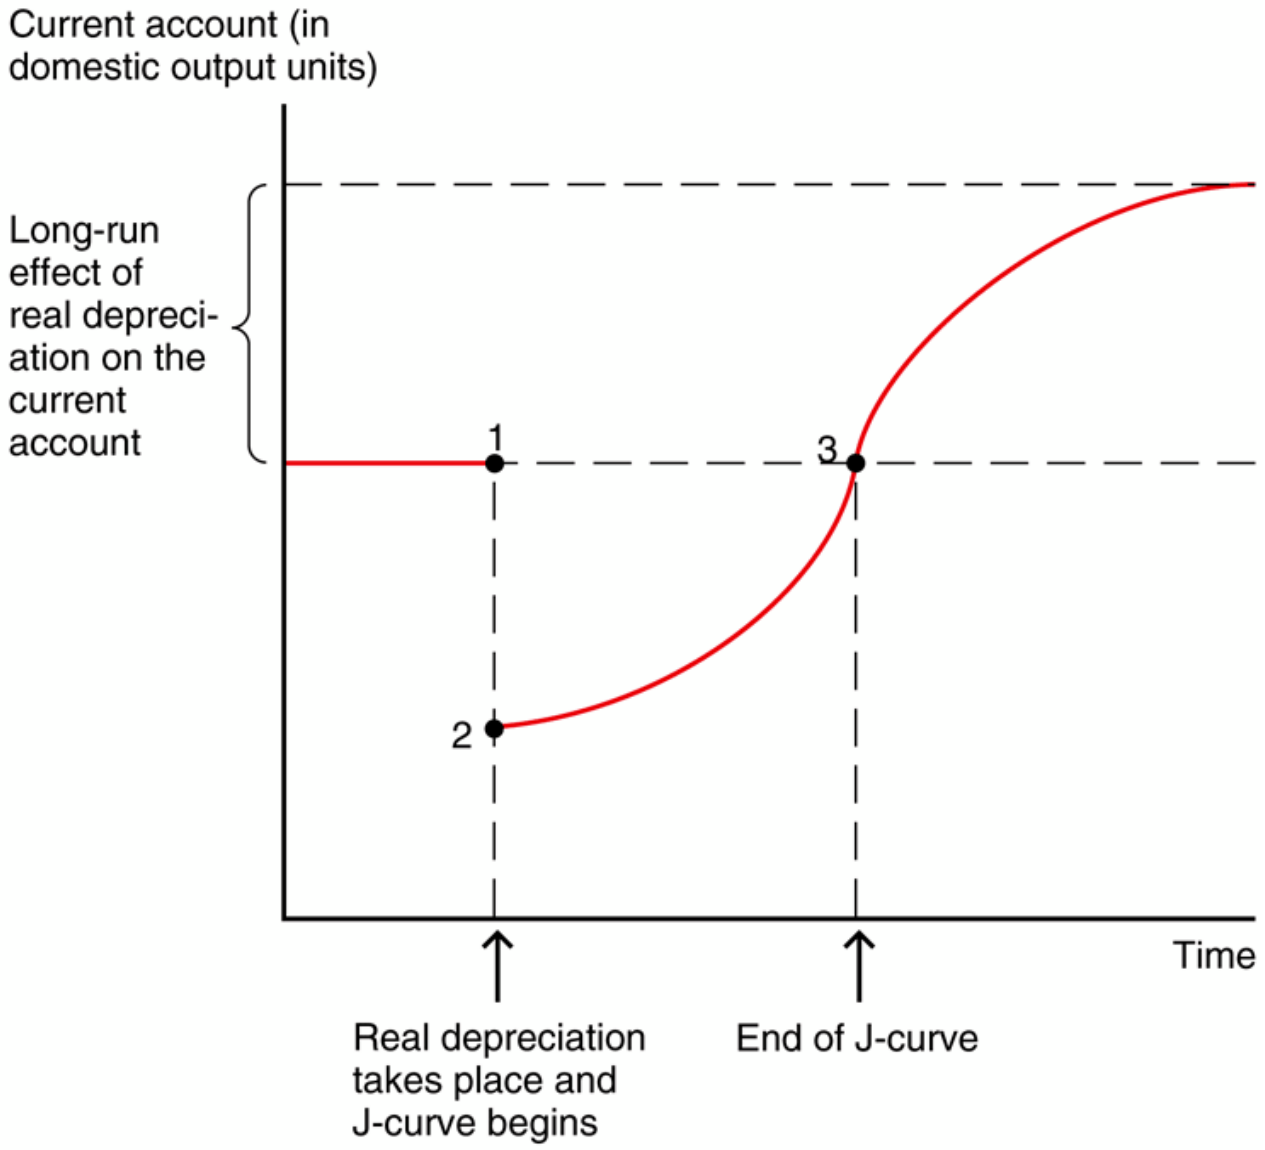
Fig. 17-18: The J-Curve



Aggregate demand

Aggregate demand is given by:

$$D = C\ (Y - T) + G + I + CA(\frac{EP^*}{P}, Y^*, Y - T) \Rightarrow$$

This implies:

$$D = D(\frac{EP^*}{P},\ Y - T, G, I, Y^*)$$

$$\frac{EP^*}{P} \uparrow \Rightarrow D \uparrow$$

$$Y - T \uparrow \Rightarrow D \uparrow$$

$$G \uparrow \Rightarrow D \uparrow$$

$$I \uparrow \Rightarrow D \uparrow$$

$$Y^* \uparrow \Rightarrow D \uparrow$$

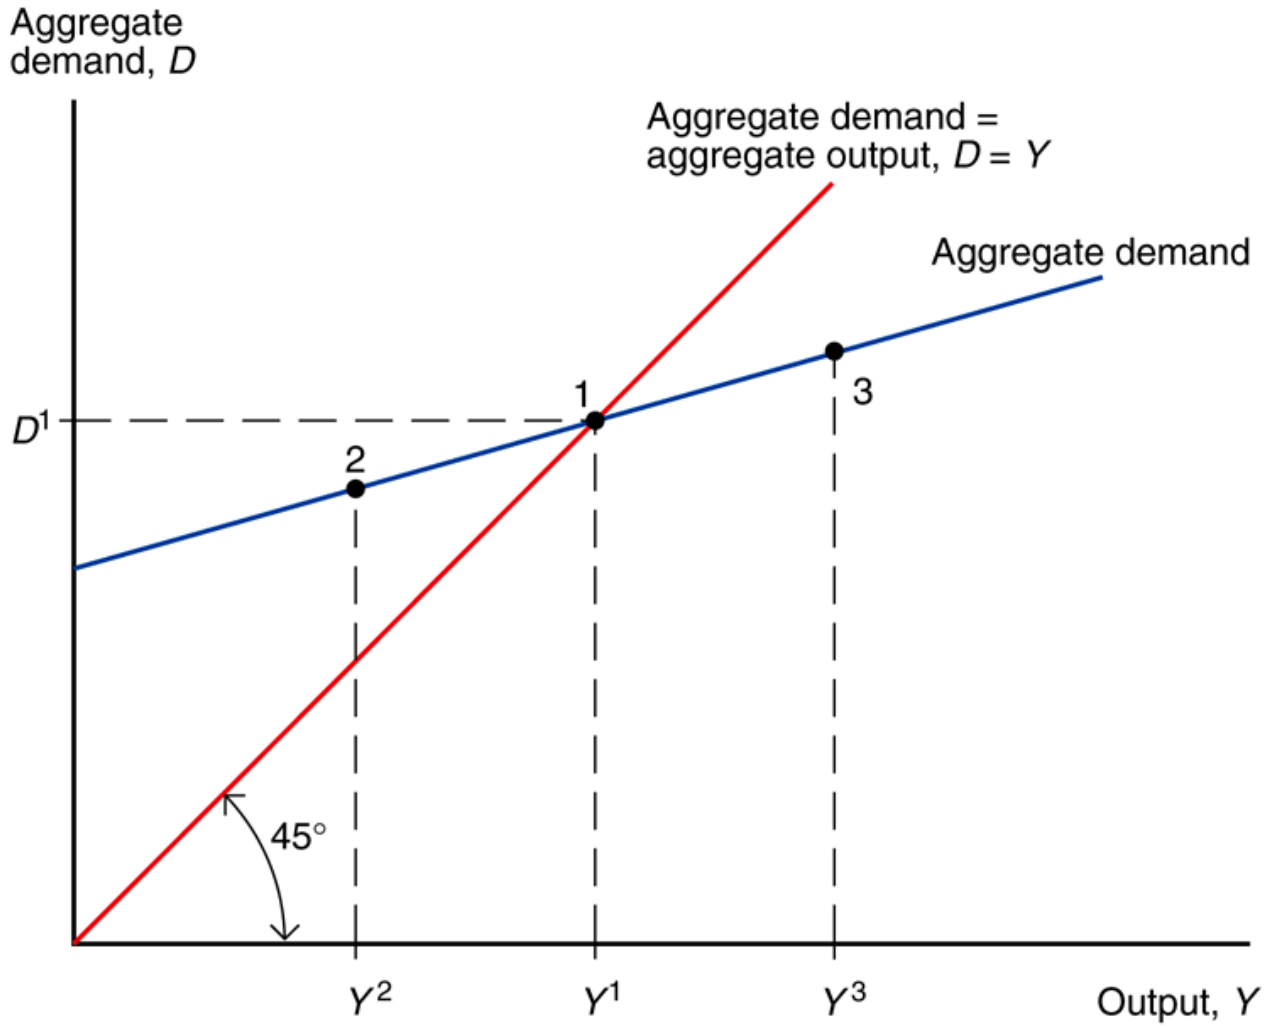

Fig. 17-3: Output Effect of a Currency Depreciation with Fixed Output Prices

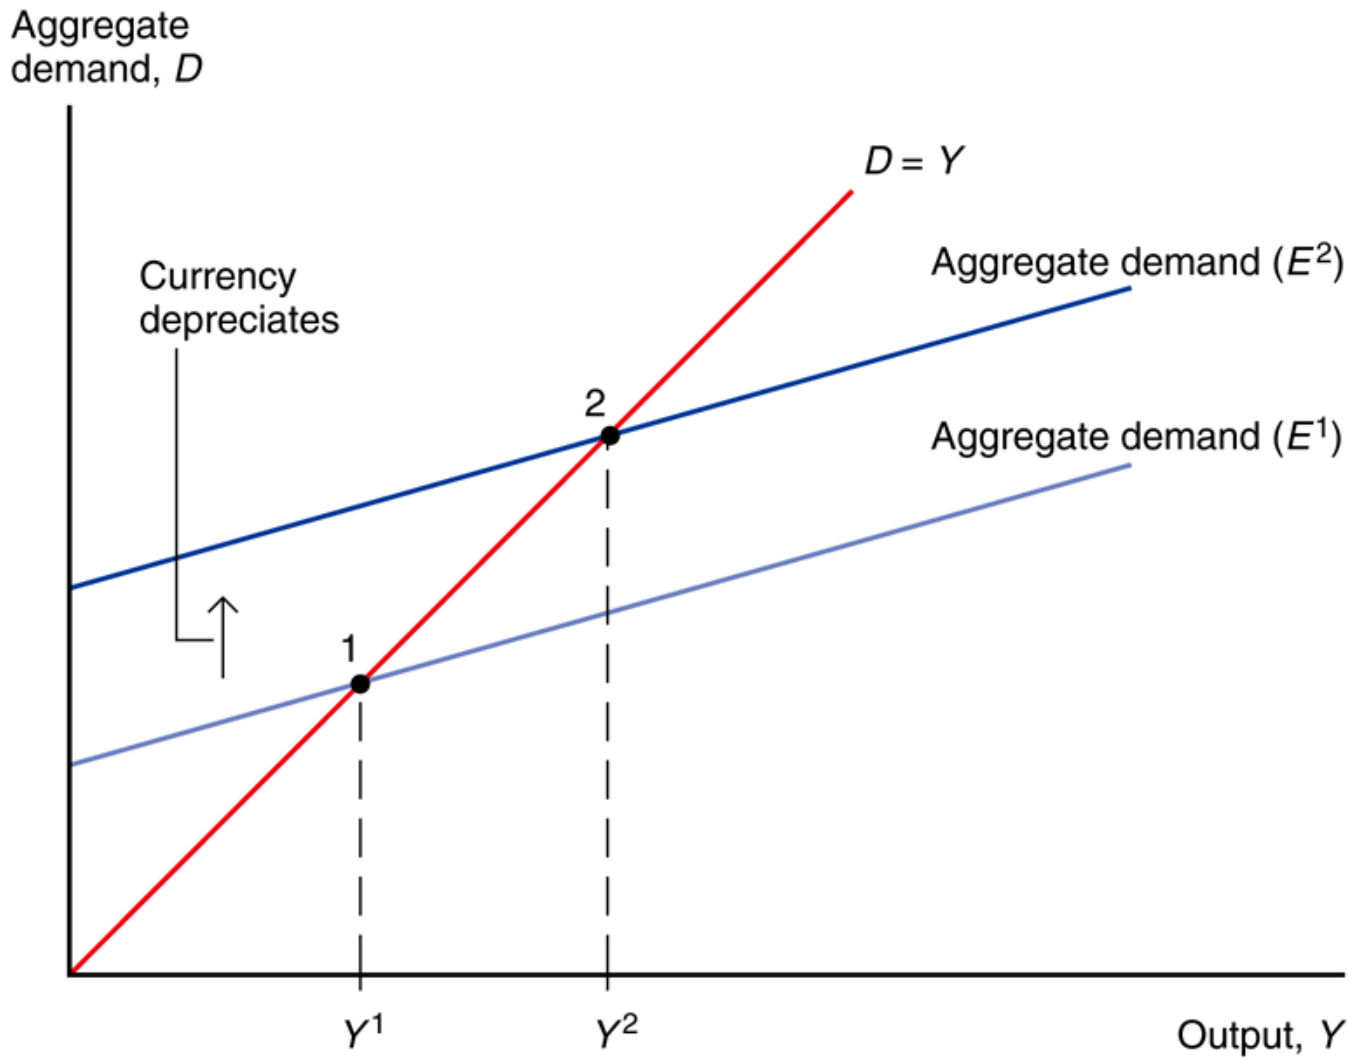

Fig. 17-4: Deriving the *DD* Schedule

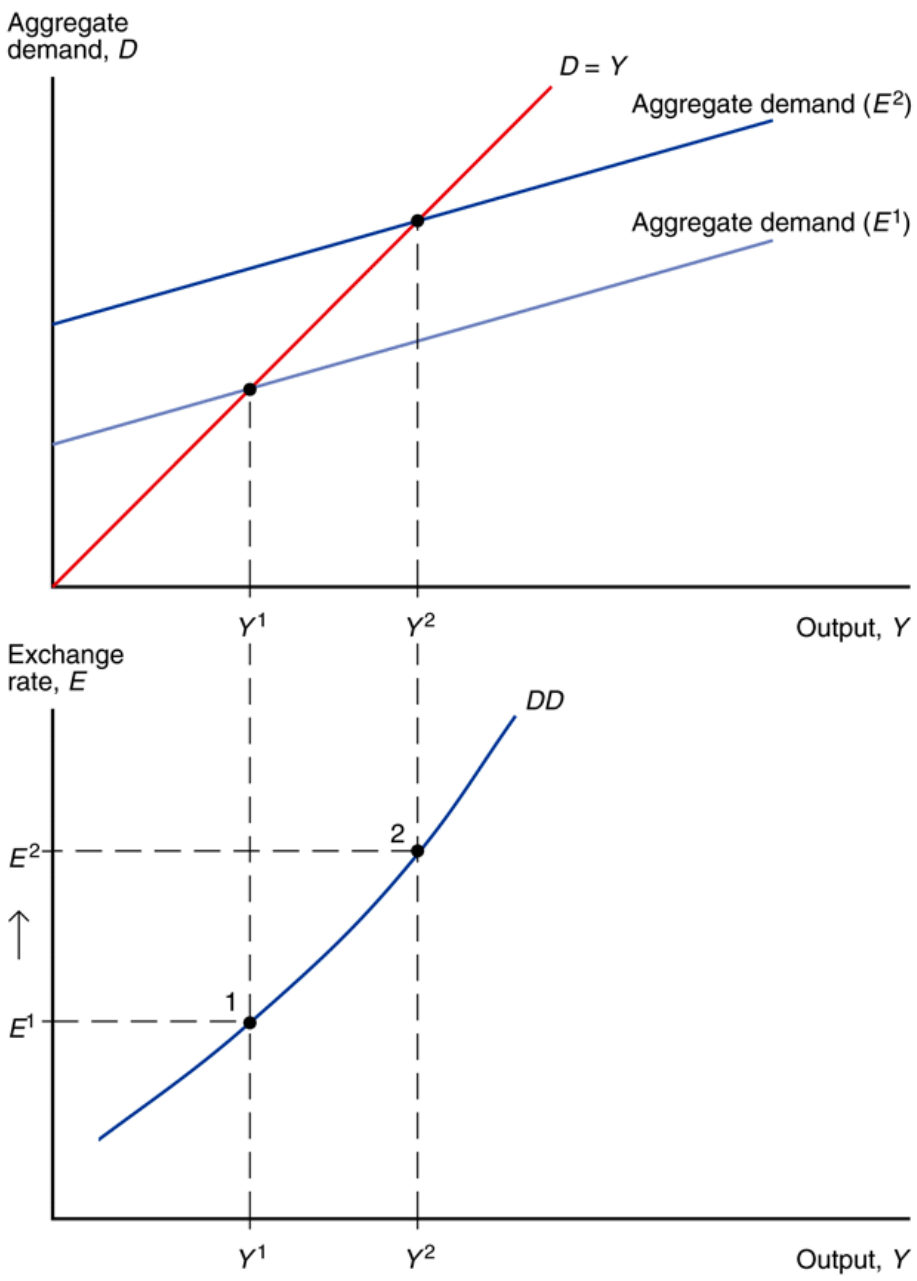

Fig. 17-5: Government Demand and the Position of the *DD* Schedule

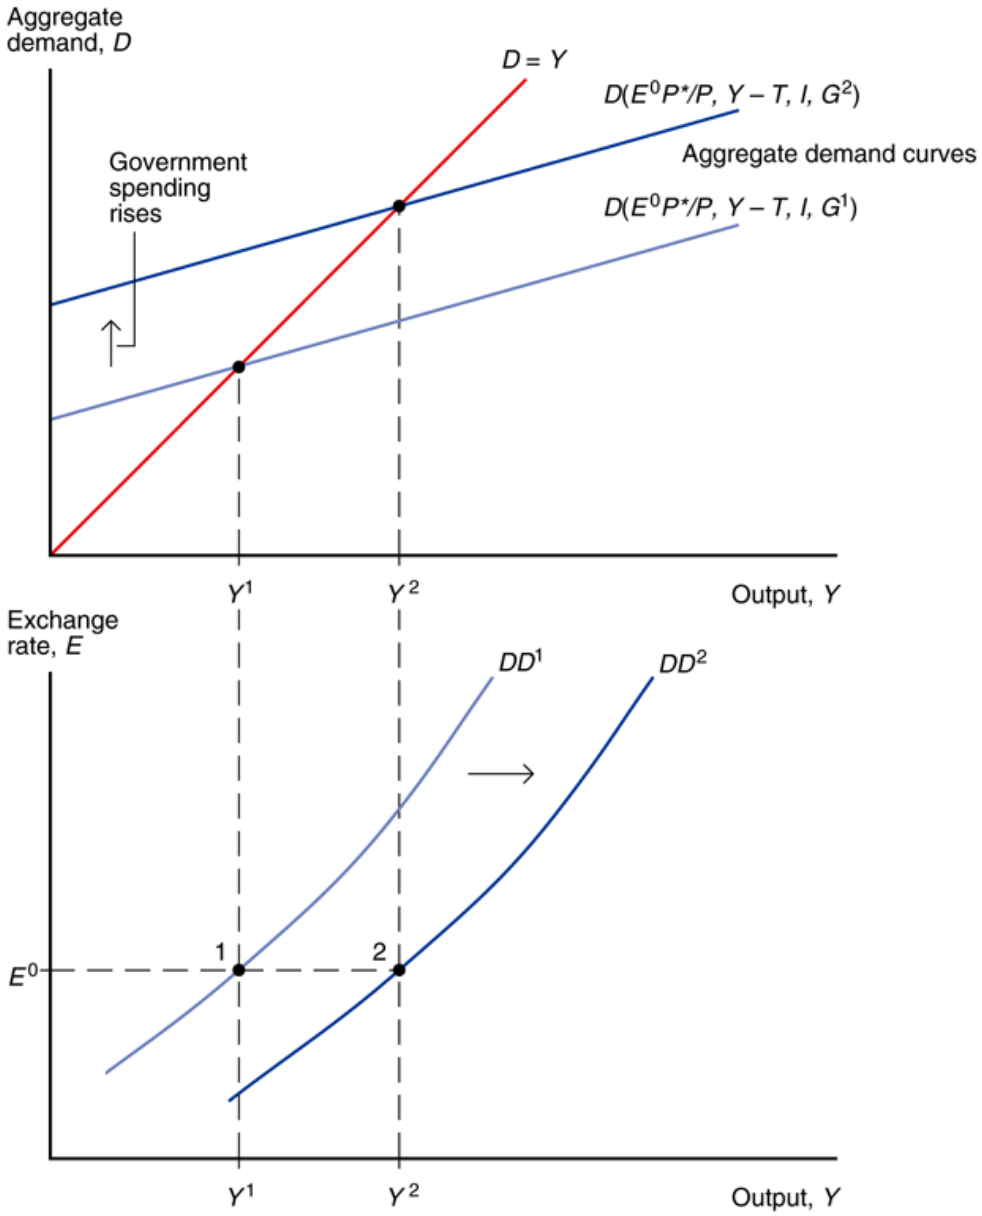

Changes shifting the DD-curve to the right

1. **An increase in government expenditure ($G\uparrow$)**
2. **A reduction in the tax ($T\downarrow$)**
3. **An increase in investment ($I\uparrow$)**
4. **A reduction in the domestic price level ($P\downarrow$)**
5. **An increase in the foreign price level ($P^*\uparrow$)**
6. **An increase in foreign income ($Y^*\uparrow$)**

Equilibrium in asset markets

1. Foreign currency market (interest rate parity)

$$R = R^* + (E^e - E)/E$$

2. Money market

$$M^s/P = L(R, Y)$$

Fig. 17-6: Output and the Exchange Rate in Asset Market Equilibrium

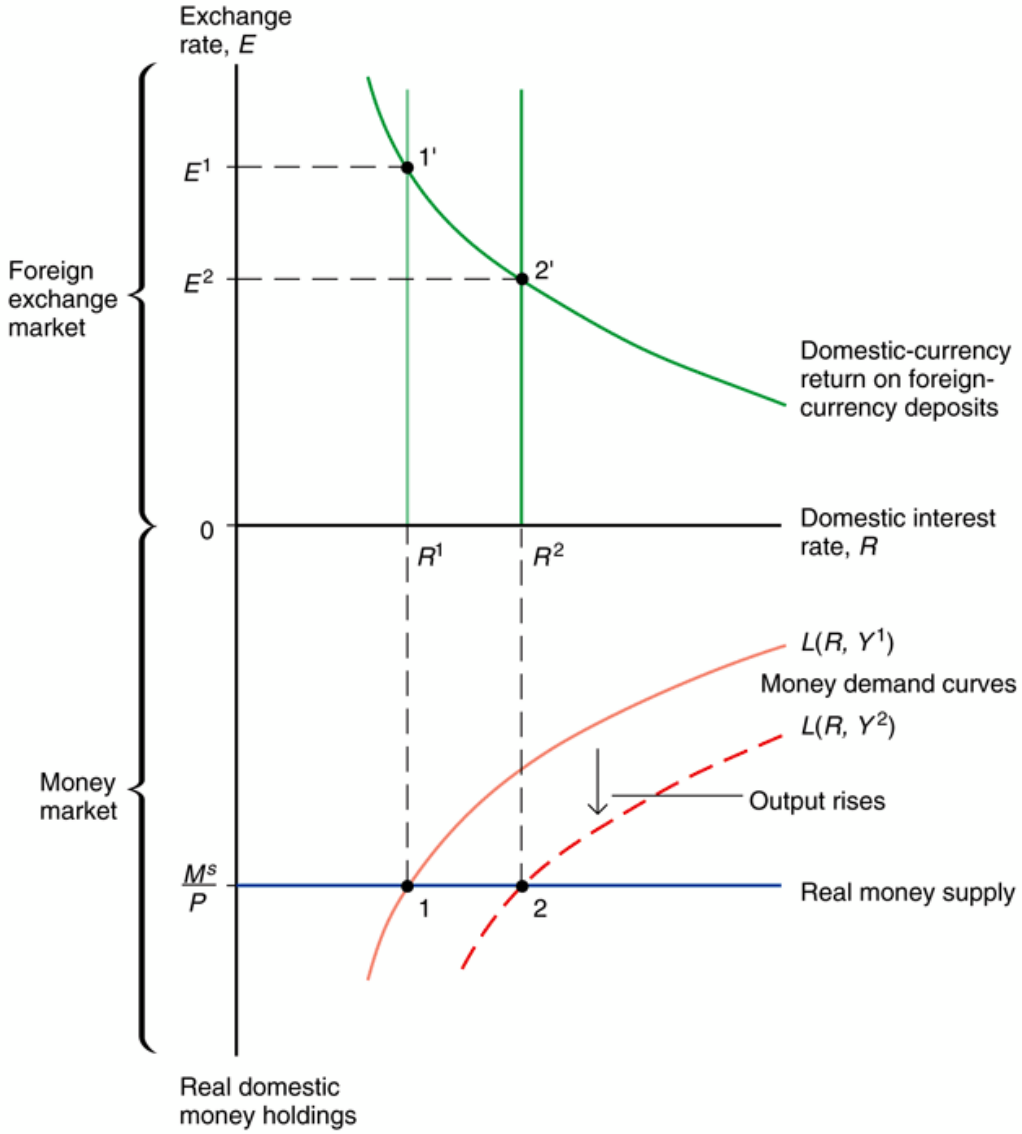

Fig. 17-7: The *AA* Schedule

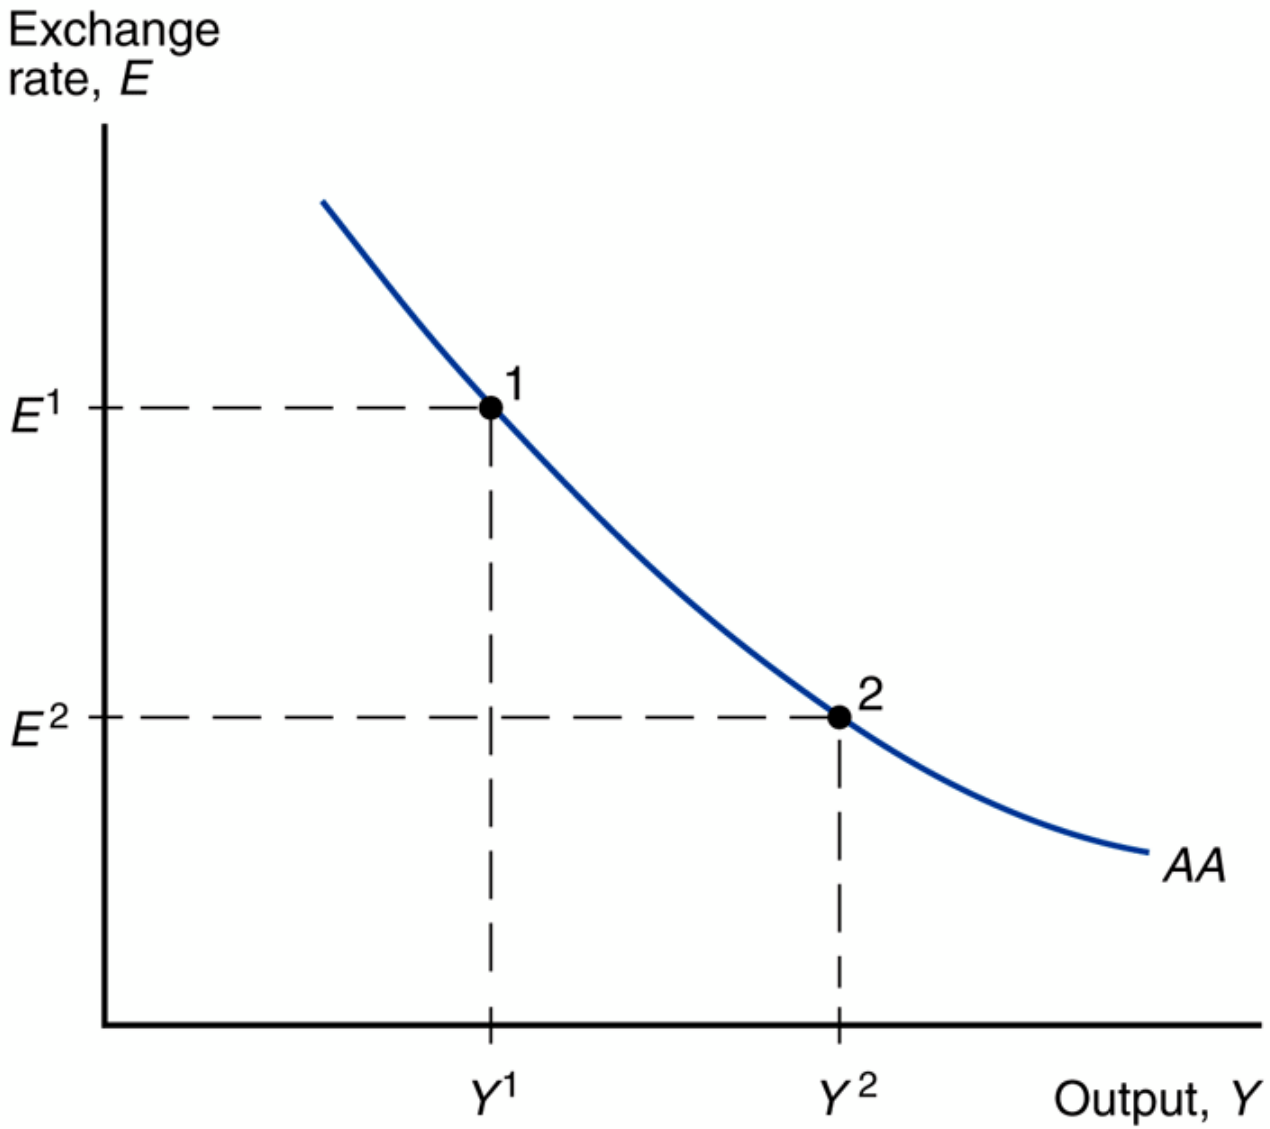
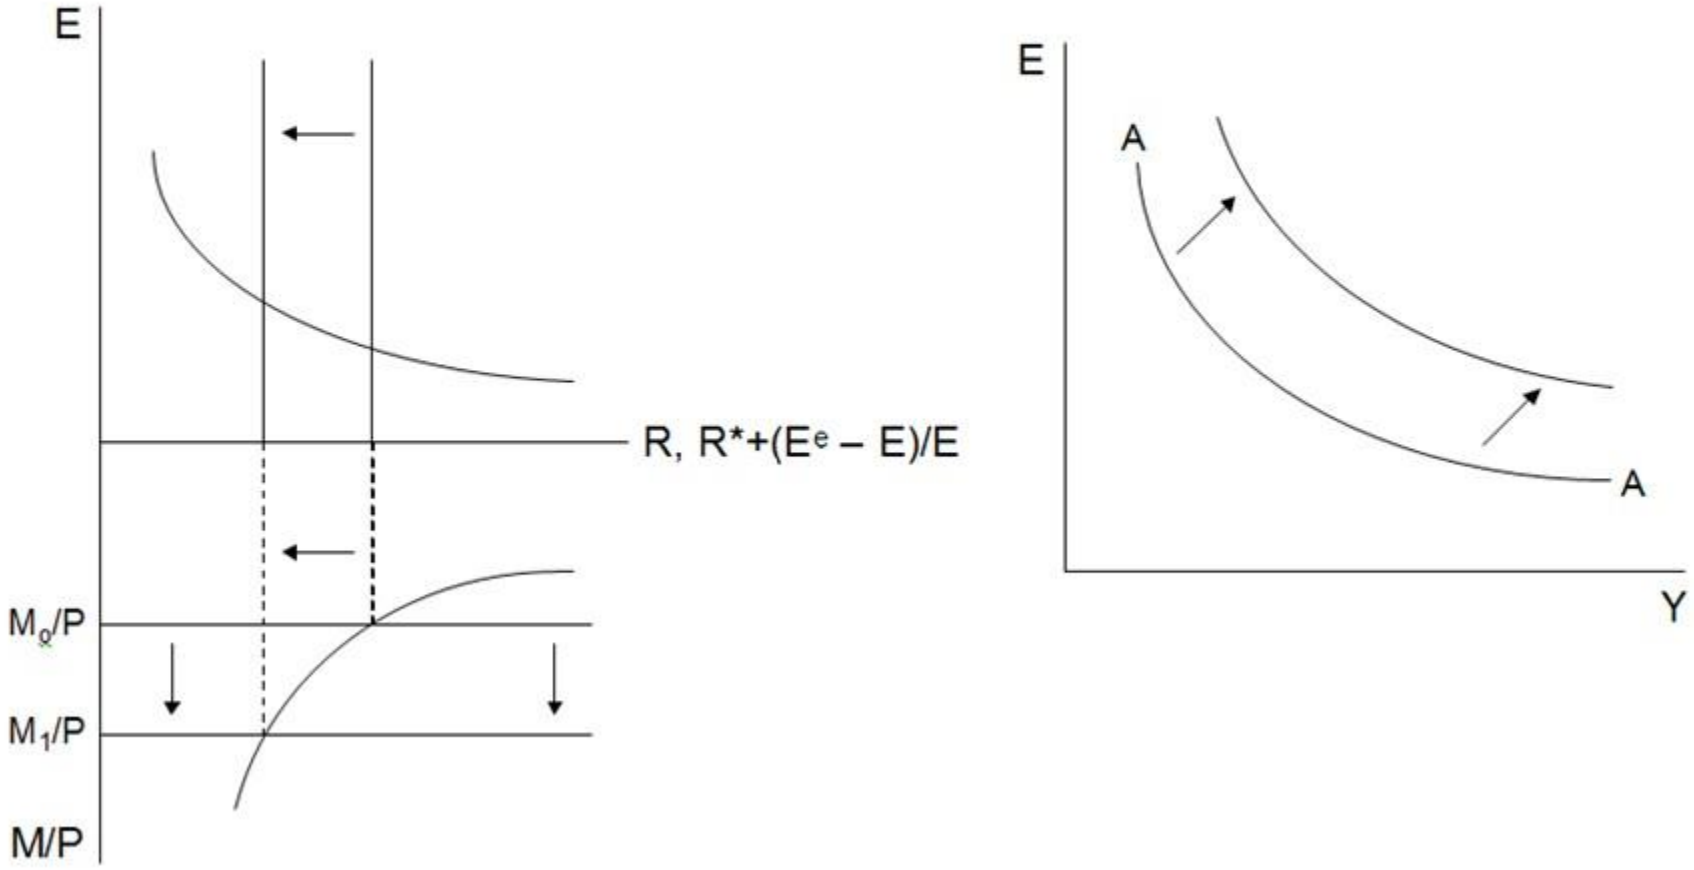


Factors shifting the AA-curve upwards

1. **An increase in money supply ($M^s\uparrow$)**
2. **A reduction in the price level ($P\downarrow$)**
3. **An expected future depreciation ($E^e\uparrow$)**
4. **A higher foreign interest rate ($R^*\downarrow$)**

AN INCREASE IN MONEY SUPPLY, A REDUCTION OF THE PRICE LEVEL



AN EXPECTED DEPRECIATION, AN INCREASE IN THE FOREIGN INTEREST RATE

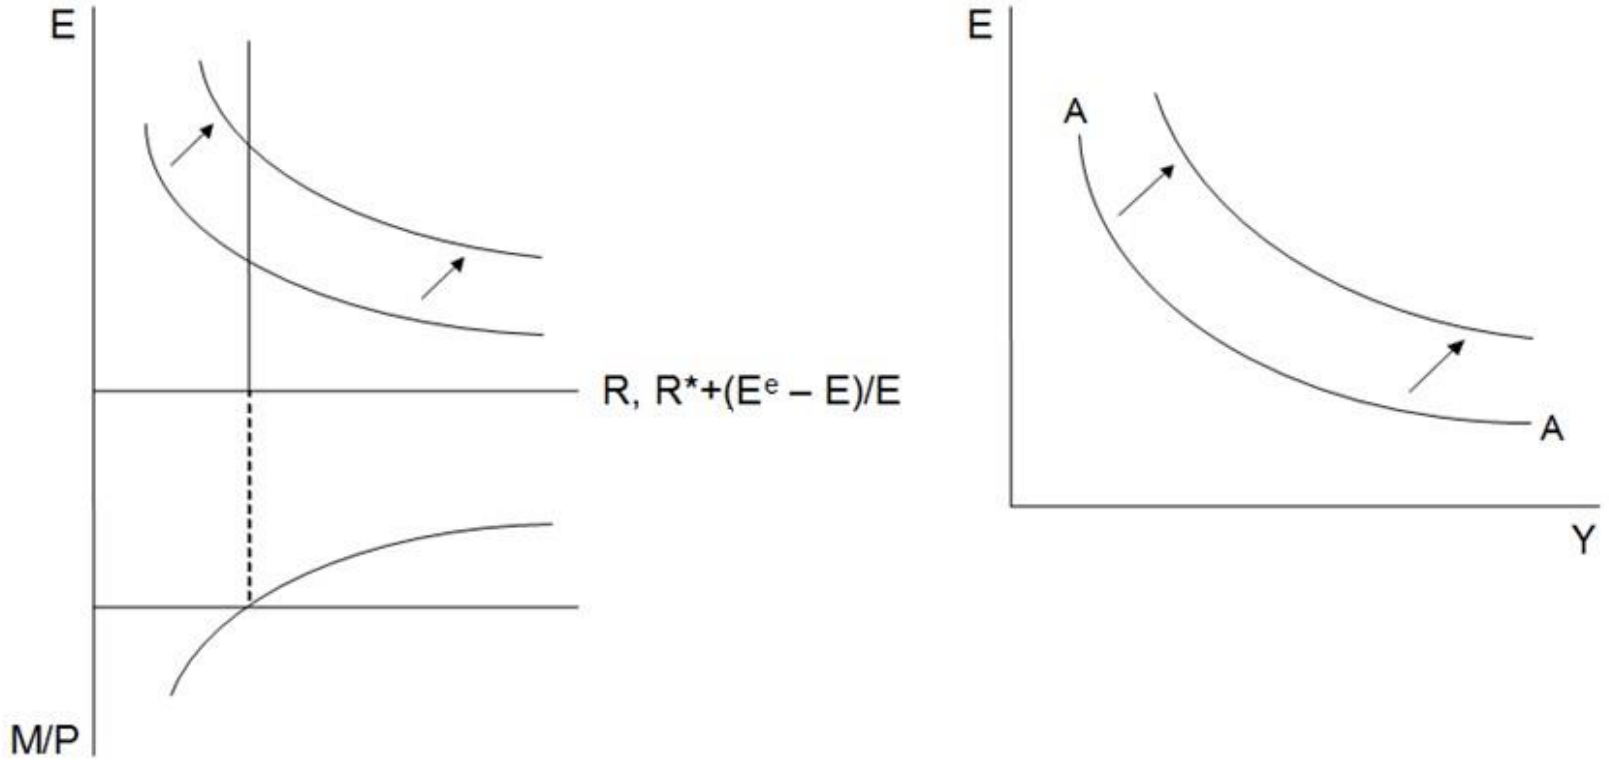


Fig. 17-8: Short-Run Equilibrium: The Intersection of *DD* and *AA*

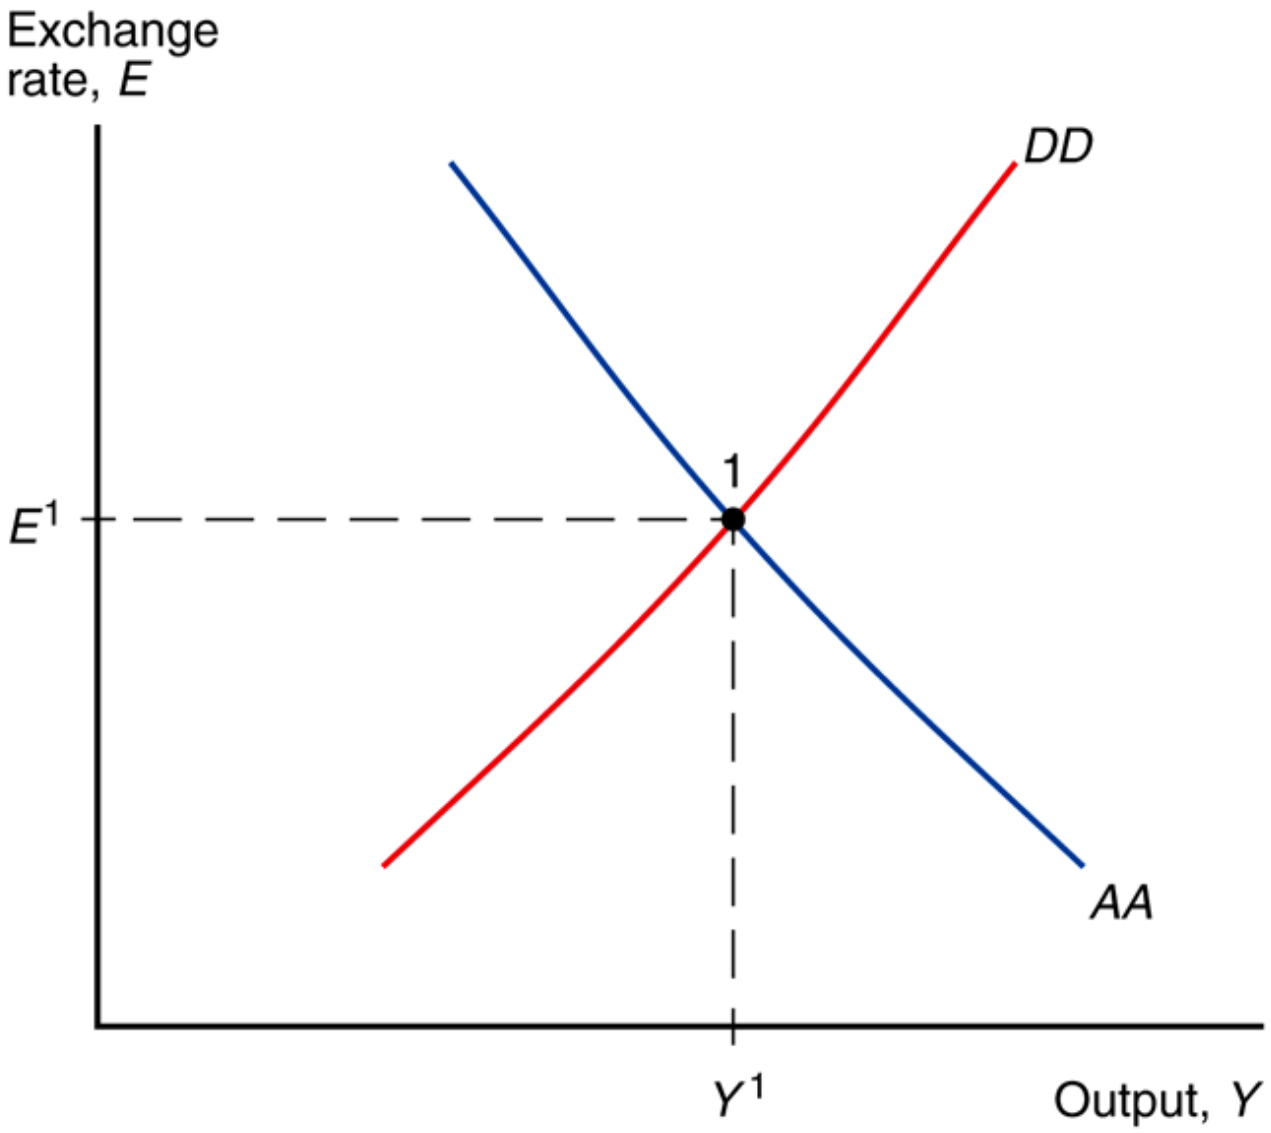

Fig. 17-9: How the Economy Reaches Its Short-Run Equilibrium

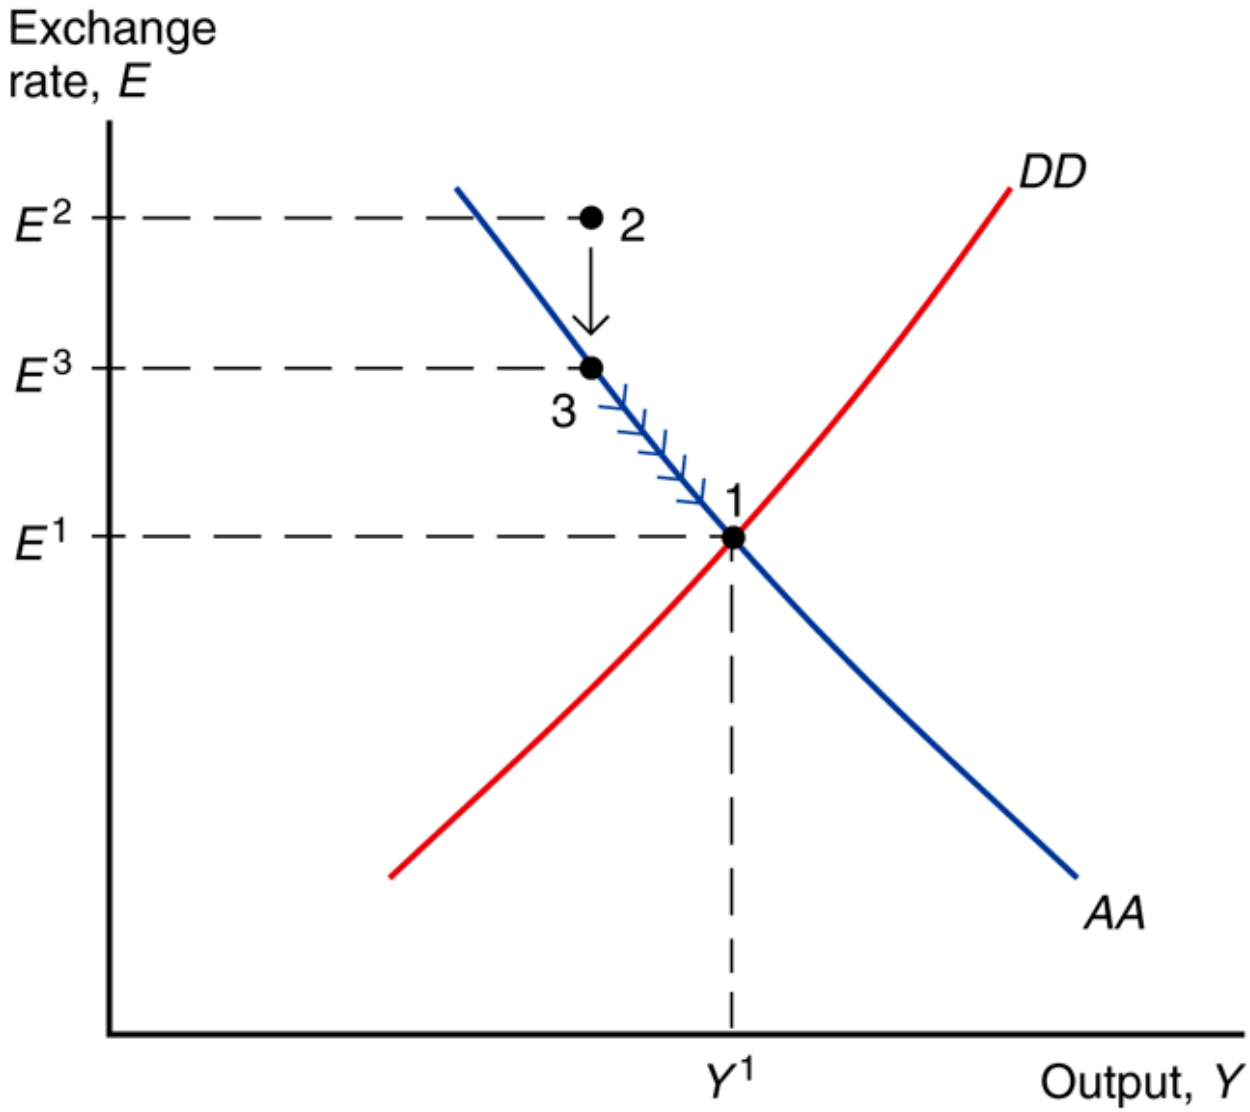

A temporary change in the money supply

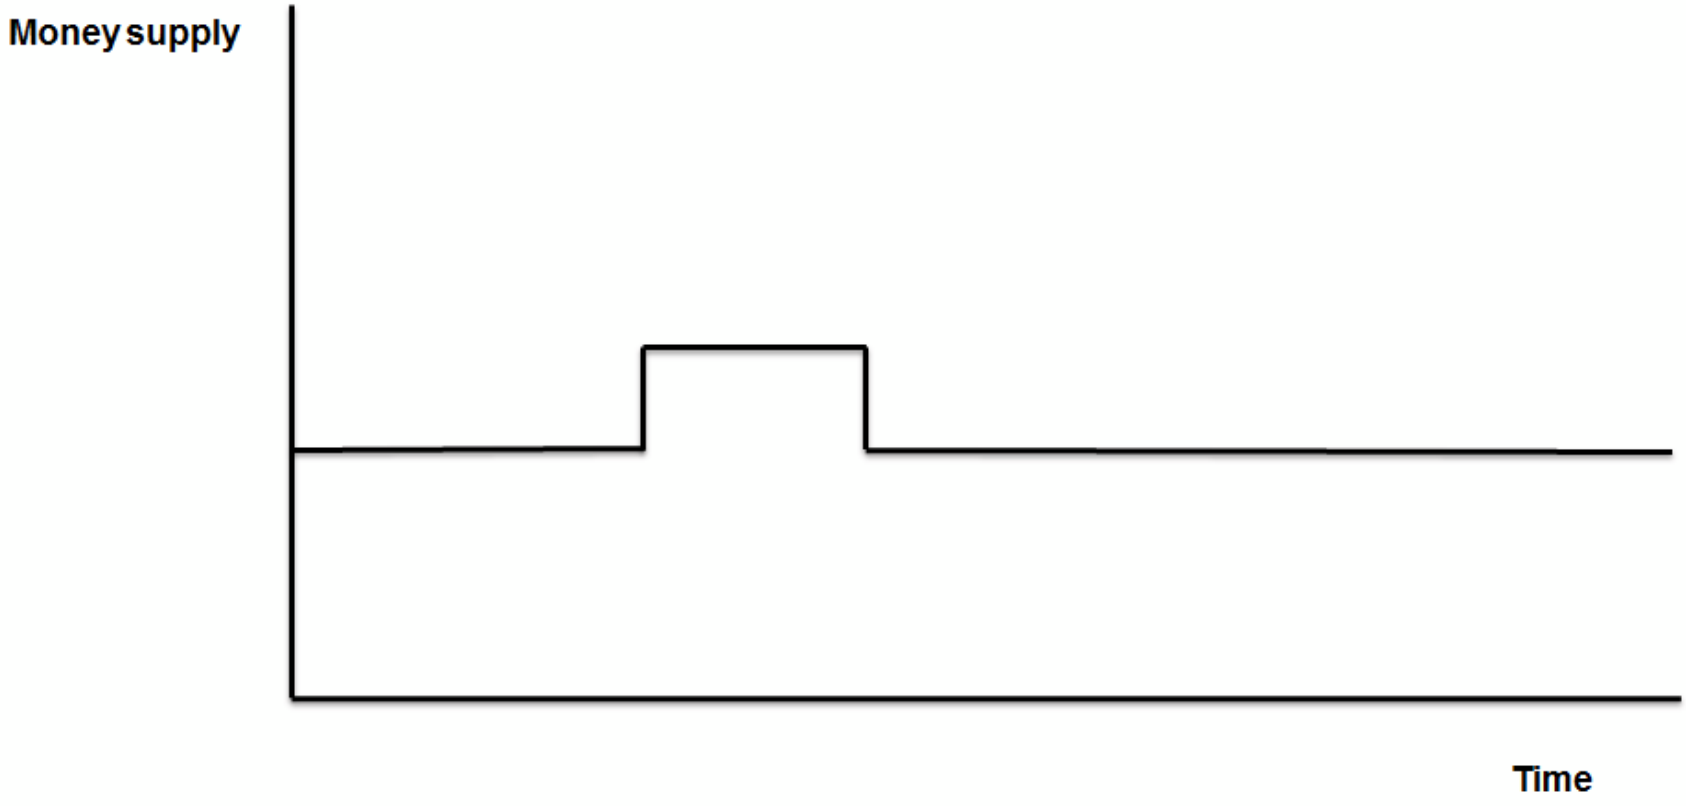

Fig. 17-10: Effects of a Temporary Increase in the Money Supply

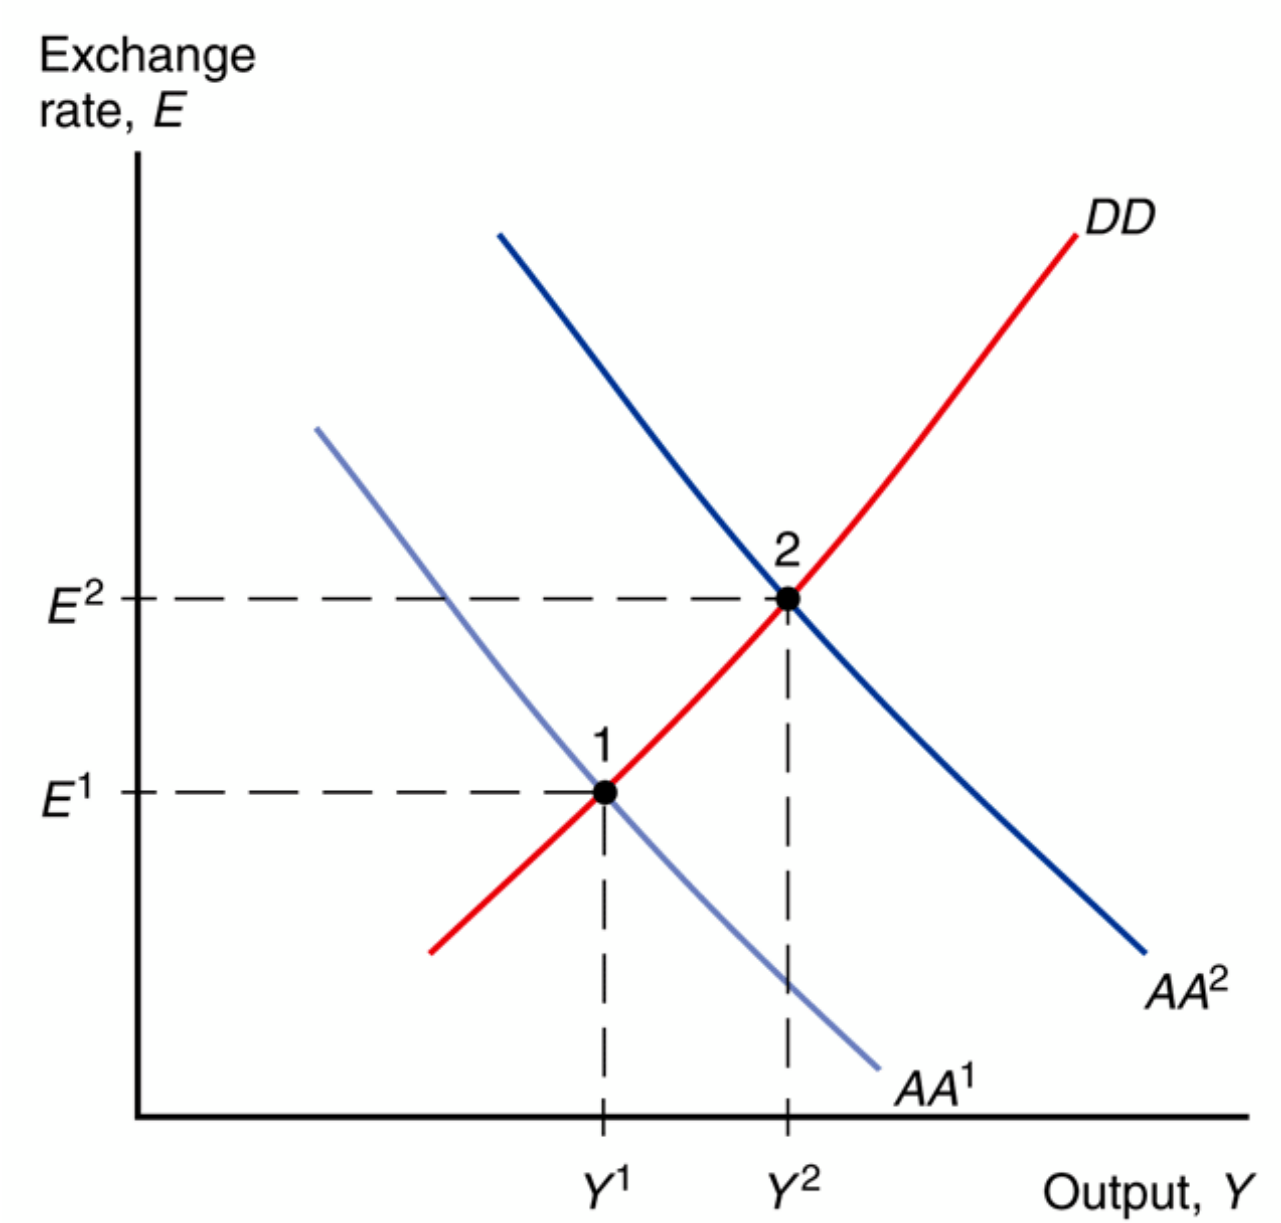

Fig. 17-11: Effects of a Temporary Fiscal Expansion

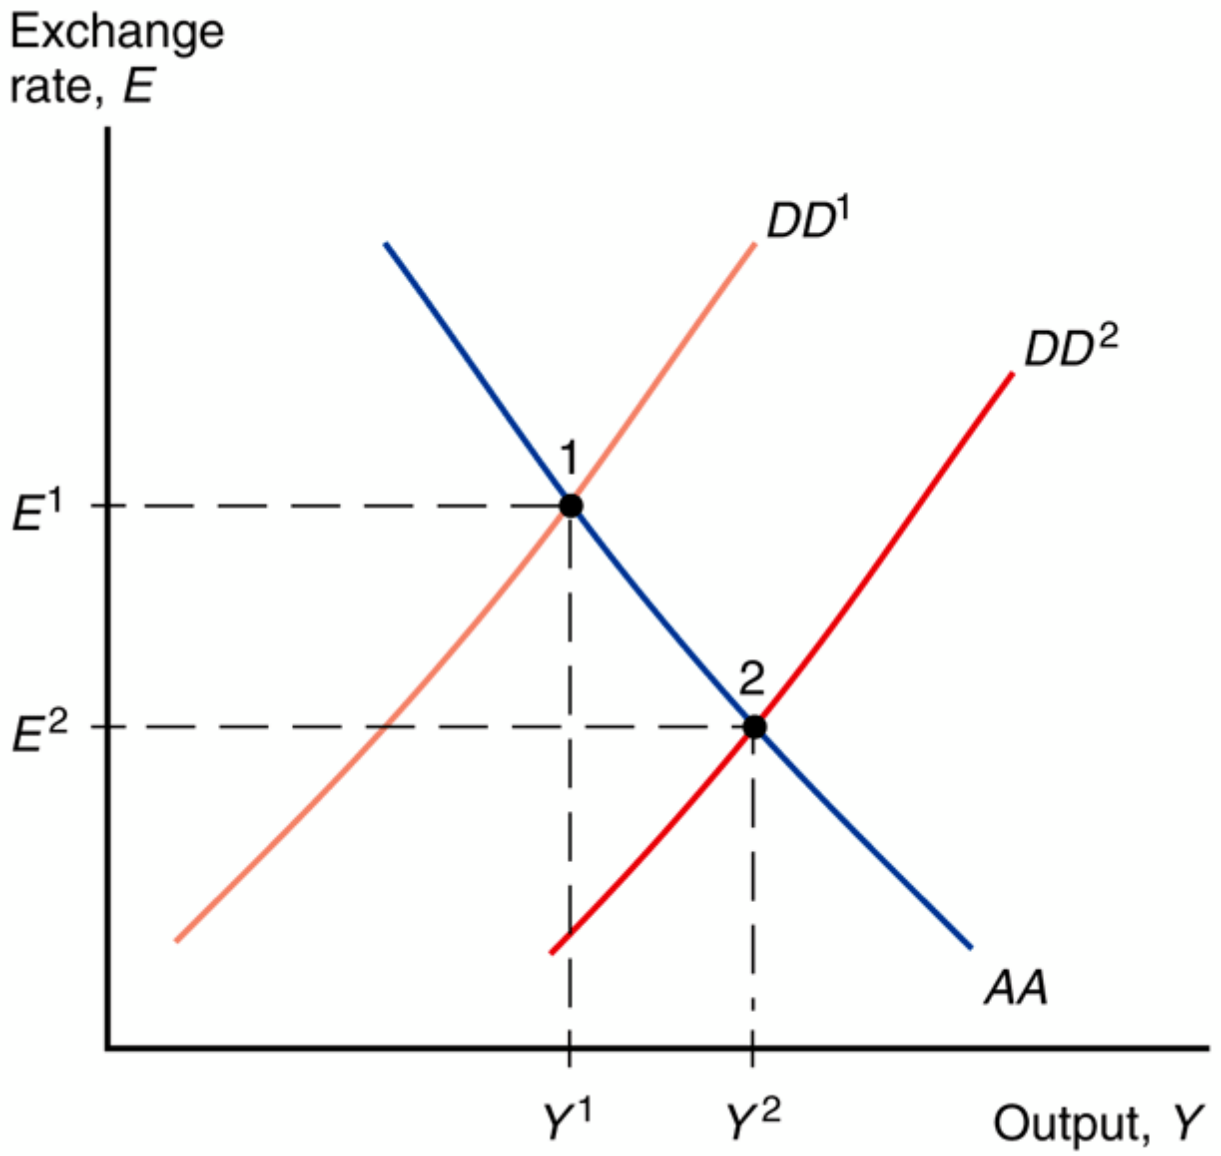

Fig. 17-12: Maintaining Full Employment After a Temporary Fall in World Demand for Domestic Products

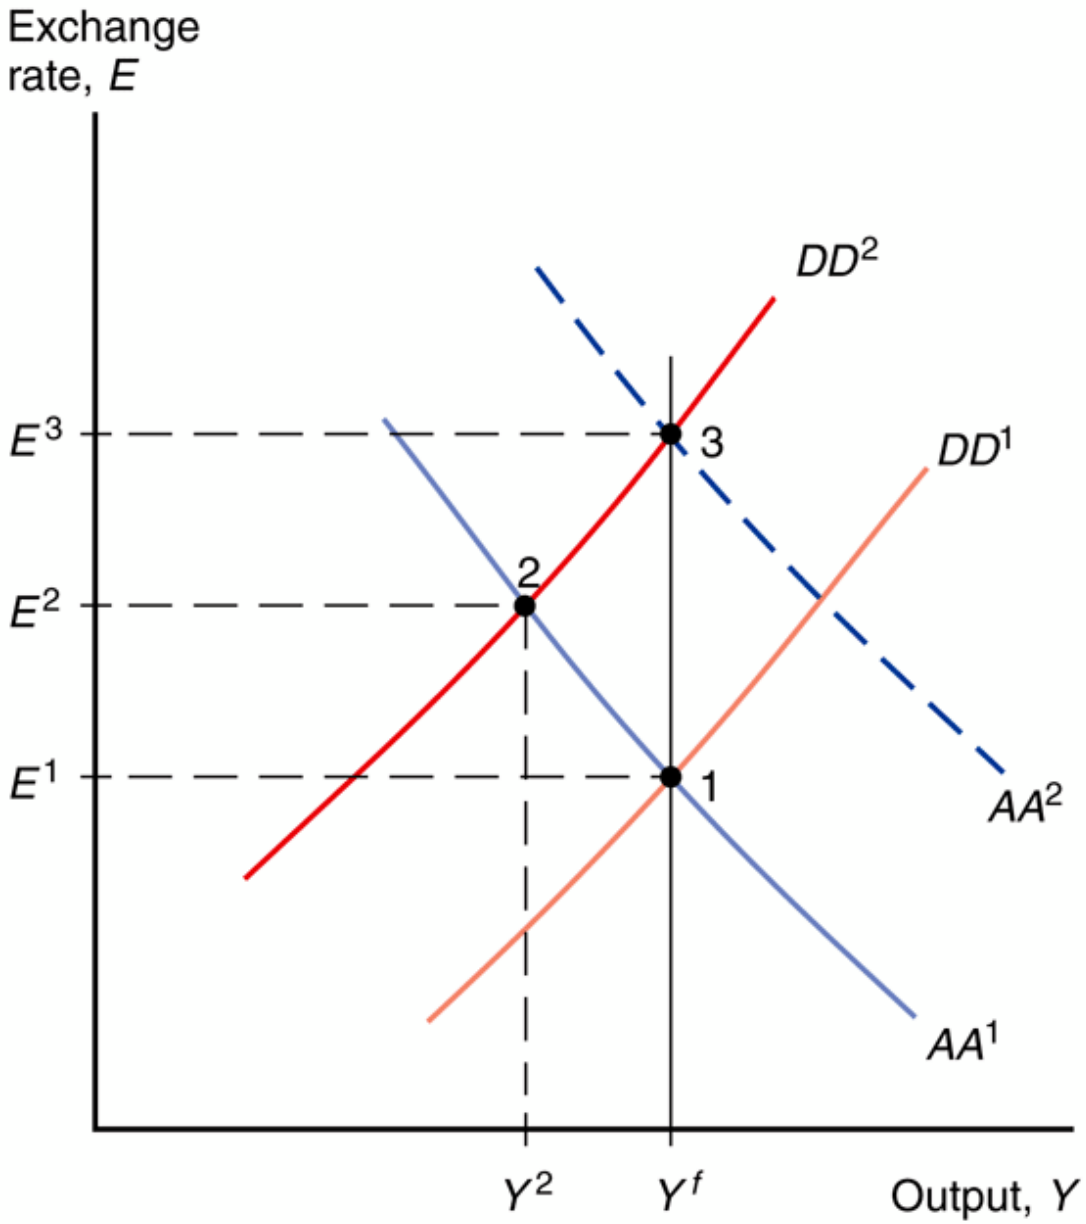

Problems with stabilisation policy

- **Policies can easily become too expansionary on average (”inflation bias”)**
- **It is difficult *ex ante* to identify disturbances and how strong they are**
- **An expansionary fiscal policy can contribute to permanent budget deficits: US and the euro zone in the recent recession**
- **Policy lags**
    - **It takes time to change policy and before it affects the economy**
