Abstract

Economists generally assume that the state has sufficient institutional capacity to support markets and levy taxes, assumptions which cannot be taken for granted in many states, neither historically nor in today's developing world. Our paper develops a framework where "policy choices" in market regulation and taxation are constrained by past investments in the legal and fiscal capacity of the state. We study the economic and political determinants of such investments and find that legal and fiscal capacity are typically complements. Our theoretical results show that, among other things, common interest public goods, such as fighting external wars, as well as political stability and inclusive political institutions, are conducive to building state capacity of both forms. Our preliminary empirical results uncover a number of correlations in cross-country data which are consistent with the theory.

*We are grateful to three anonymous referees, Daron Acemoglu, Oriana Bandiera, Jeremy Bulow, Steve Coate, Jim Fearon, Avner Grief, Patrick O'Brien, Guido Tabellini, Andrei Shleifer, Barry Weingast, and numerous seminar participants for useful comments and discussions. We also thank Giovanni Favara and Mick Keen for kind providing us with data, Dario Calda for excellent research assistance, and CIFAR, the Swedish Research Council, the ESRC, and the Tore Browaldh Foundation for generous financial support.

1 Introduction

Historians see the evolution of state capacity – especially the capacity to raise taxes – as a central fact to be explained, whereas economists typically assume that such institutional capacity exists. An intriguing argument by political historians (see, e.g., Tilly, 1990) holds that state capacity evolved historically over centuries in response to the exigencies of war. War placed a premium on sources of taxation and created incentives for governments to invest in revenue-raising institutions.¹

More recent historical links between the introduction/development of modern income tax systems and the onset or risk of war also provides some interesting clues. For example, Britain first introduced an income tax in the budget of 1798 given the pressure on its public finances due to the Napoleonic war. The U.S. first introduced a form of income taxation in 1861 during the civil war and the Internal Revenue Service (IRS) was founded at the same time. Both countries significantly extended their income tax systems during the first and second world wars; in Britain, for example, the pay-as-you-earn method of tax collection was introduced in 1944. In Sweden, a system of relatively uniform permanent taxation of land and temporary taxation of wealth goes back as far as the 13th century. Sweden first introduced a general income tax in 1861 and an expanded progressive income tax in 1903, in both cases with the motive to increase military expenditures. Our analysis will suggest that the significance of war and military spending in state capacity building comes from the fact that it is an archetypical public good representing broadly common interests for citizens.

In contrast to these historical lessons, traditional economic theory presumes sufficient institutions not only to tax citizens, but also to sustain markets. The Arrow-Debreu model implicitly assumes a government that flawlessly enforces contracts. Studies of optimal taxation explicitly acknowledge informational constraints, but implicitly assume a bureaucracy able and willing to enforce any tax policy respecting those constraints. Positive analyses in political economics of how the power to tax or regulate is chosen in a political equilibrium with collective choice makes the same implicit assumption. As this starting point cannot safely be taken for granted in many states,

¹O'Brien (2005) argues that British naval hegemony over nearly three hundred years was rooted in the a superior power to raise taxes. Brewer (1989) and Hoffman and Rosenthal (1997) discuss the link between the development of taxation and political institutions, such as parliamentary democracy.

neither historically nor in the developing world of today. One motivation for our paper is to fill that lacuna in the theoretical literature.

Another motivation is to provide answers to some empirical questions in development. Why are rich countries also high-tax countries with good enforcement of contracts and property rights? Why do parliamentary democracies have better property rights protection and higher taxes than presidential democracies? Why is it so hard to find evidence in aggregate data that high taxation is negatively related to growth, while there seems to be good evidence that poor property rights protection is?

If state capacities do indeed impose effective constraints, we will be able to gauge them through current measures of taxation and market development. Figure 1 illustrates a positive correlation between measures of the power to tax and of financial development. It graphs the share of government revenue raised from income taxes as a share of GDP against the average private credit to GDP ratio (both measured as a percentage in 1995, see Section 5 for more on the underlying data). The figure also illustrates a positive correlation between both these measures and income per capita. Countries below median income per capita marked by solid dots and countries above median income per capita marked with hollow dots. Clearly, poorer countries are scattered to the south west in the graph, while the richer ones cluster in the north east. Our theory will emphasize that nothing causal can be read into these correlation patterns. Whatever the explanation for these cross-country correlations, however, they are hard to square with simplistic notions that having a small government is a precondition for being a rich and developed nation; they rather suggest that higher taxation and financial development have common underlying causes.

In this paper, we propose a model to better understand some of these historical, theoretical, and empirical issues. The contribution is to put together a number of factors in a unified framework. Of course, we cannot build a model of everything, so we focus on two specific aspects of state capacity. In our framework, regulation of market supporting measures and tax rates are endogenous policy choices. But these are constrained by the state's "legal" and "fiscal" capacity, economic institutions inherited from the past. Current policy choices also reflect political regimes inherited from the past. We then explore the relationships between taxes and property rights, redistribution vs. the provision of public goods, income levels, and political regimes. Key to our model is to treat the state's legal and fiscal capacity as

ex ante investments under uncertainty.²

One of our central findings is that investments in legal and fiscal capacity are often complements. On the analytical side, this complementarity allows us to use results from monotone comparative statics, which considerably simplifies the analysis. On the substantive side, the analysis provides a complete set of determinants of investments in state capacity including the importance of common interest public goods, the level of wealth, the gains from trade in financial markets, political stability and protection of minorities, and the distribution of economic and political power. Moreover, the complementarity suggests a new way of thinking about the interaction between economic growth and the size of government. On the empirical side, the complementarity leads to the prediction that we should find common determinants of both types of state capacity. We find support for this idea in a preliminary look at the data.

Our paper makes contact with several strands of literature. It is clearly related to the above-mentioned body of work on the economic and political history of the state. While that literature is mainly focused on the state's capacity to raise revenue, it does not emphasize – as we do – the links with the state's capacity to support market institutions. The same is true of the emerging literature in public finance that takes seriously issues of compliance as a constraint on effective taxation (for an overview see Slemrod and Yitzhaki, 2002).

Our paper is also related to the recent work seeking to explain the institutions that support financial markets, such as the protection of minority shareholders or private property rights (see, for example, La Porta et al, 1998, Rajan and Zingales, 2003, Acemoglu and Johnson, 2005, and Pagano and Volpin, 2005). As in that work, our analysis treats market-supporting institutions as endogenous. But we analyze market supporting institutions together with taxation, which allows us to address the crucial "Coase theorem" question why a particular ruling group would not provide maximum efficiency of markets and further its own selfish interests through redistributive taxation.³ We also make a clear distinction between economic institutions and policy choices constrained by these institutions. This distinction allows

²The general idea of studying dynamic investments in institutions which affect subsequent policy choices is similar in spirit to Lagunoff (2001), and to the literature on strategic debt issue (Persson and Svensson, 1989).

³Acemoglu (2006) considers the spillovers to regulatory policies of the state's capacity to tax, but treats the latter as exogenous.

us to consider how economic and political factors shape economic institutions.⁴

The closest antecedent to this paper is Acemoglu (2005) which develops a model where a government raises taxes to spend on a mixture of transfers to the ruler and productivity-enhancing public goods. Spending on public goods increases future tax revenues. Weak states where rulers have short time horizons spend too little on productive public goods, while strong states where rules have too much security of tenure blunt accumulation incentives. Also related is Acemoglu, Ticchi and Vindigni (2007) which studies the role of bureaucracies in creating (in)effective states.

As already mentioned, we build a simple two-period model where past investments in legal and fiscal capacity constrain current policy decisions. Section 2 formulates this model and studies equilibrium private decisions. Section 3 analyzes policy choices for given institutions, when these choices are made by a utilitarian planner or by self-interested governments that can be replaced. In Section 4 we analyze the optimal and equilibrium investments in legal and fiscal capacity. We present comparative statics for the economic and political determinants of legal and fiscal capacity and spell out the implications for economic growth. Section 5 presents some empirical evidence. Section 6 concludes.

2 Model and Private Choices

We construct a simple intertemporal model with two main building blocks – trade in a private capital market and taxing/spending by government.

Basics To allow for investment in as simple a way as possible, there are two periods $s \in \{1, 2\}$. Markets are open in both periods and consumers cannot save. Preferences of private agents are linear in private consumption, as well as in government spending (see below).

In each period the government in power makes policy decisions on regulation, taxes and spending. In period 1, the government makes investments in institutions, knowing that the world ends in period 2. This simple framework

⁴On this point, our approach is related to the theoretical and empirical work by Cukierman, Edwards and Tabellini (1992) on how the use of seignorage depends on the efficiency of the tax system, and how the strategic choice of the latter depends on political stability and polarization.

captures the essentials of a representative time period within a fully specified dynamic model.

To model conflicting interests in the simplest possible way, we assume that there are two groups, $J \in \{A, B\}$. Group membership is due to some attribute that is observable by everybody, including the government. These groups make up shares β^A, β^B of the population. For simplicity, all agents within each group have the same wealth level, w^J .

Production Opportunities To give a rationale for the capital market, we assume that individuals differ not only in publicly observable group membership, but also in privately observed production opportunities. Each person can engage in a project where the gross return for individual I is $r_{I,s} \in \{r_L, r_H\}$ and $r_H > r_L$. We denote the share of group J agents with high returns by σ^J (the same in each time period), such that type H individuals in group J make up a share $\beta^J \sigma^J$ of the total population.

Borrowing, Property Rights Protection, and Legal Capacity Entrepreneurs can expand the size of projects by borrowing in a competitive capital market. To prevent default, a member of group J can put up a share of her wealth w^J as collateral. While contracts between borrowers and lenders are upheld by the legal system, we assume that only a share $p_s^J \leq 1$ of collateral is "effective", where p_s^J is an index for the enforcement of property rights. Since lenders (and borrowers) have linear preferences, p_s^J can be interpreted as the probability that a lender gains access to collateral in case of default. As collateralized investment will earn no less than the (gross) market return r_s in period s , someone from group J can only borrow as much as she will be expected to repay at r_s .

We model p_s^J , $J = A, B$, as a policy choice by the government which is taken before private choices are made. We say that property-rights protection is better for group J , when p_s^J is higher, as this allows more borrowing for each piece of collateral. Property-rights protection can be differentiated by observable group J , but not by unobservable type I . Group-specific protection reflects the possibility that resources put into contract enforcement may depend on the sector or geographical location of economic activity. Property rights are universal if $p_s^A = p_s^B$, i.e., when everyone in the economy has equal access to contract enforcement.

The choice of how well to enforce private property rights in period s is

constrained to the interval: $p_s^J \in [0, \pi_s]$, where the maximum protection level π_s is determined by past investments in "legal capacity". In concrete terms, this reflects legal infrastructure such as building court systems, employing judges and registering property. The initial stock is π_1 and the investment in period 1 is thus given by $\pi_2 - \pi_1$. Because there is no depreciation of legal capacity, we require $\pi_2 - \pi_1 \geq 0$. The costs of such investments are given by $L(\pi_2 - \pi_1)$, an increasing convex function with $L(0) = L_\pi(0) = 0$.⁵

The cost function $L(\cdot)$ could, for example, be dependent on the legal origin of a country: the cost of protecting property rights may be lower under common law than under civil law. Because a higher value of π_s allows for more extensive financial contracts, it allows for more credit as a share of total output. As the ratio of private (or total) credit to GDP is often used to empirically measure financial development, we expect π_s to be closely related to that measure.

It is important to note that, in our model, property rights refer to protection against risk of expropriation by other private agents and not by the government. Government expropriation is ruled out by assumption. As discussed in the concluding section, a more complete theory of how state capacity develops would also include the latter aspect of the rule of law.

Spending, Taxes, and Fiscal Capacity The other current policy instrument is taxation of the *net* (after lending or borrowing) output from investment projects. The government can only observe net output brought to the market by a member of group J , not whether the output has been derived from a high or low return project or through lending.⁶ Thus, tax rates in period s can be made group specific, t_s^J , but not project specific. We will say that the tax system is fair when both groups are taxed at the same rate: $t_s^A = t_s^B$. To allow for redistribution in the simplest possible way, we allow tax rates to be negative.

Taxation is constrained because any individual can earn a fraction $(1 - \tau_s)$ of her returns – either from projects or lending – in an informal sector where

⁵This function, as well as the cost of investing in fiscal capacity below, could be made proportional to income per capita in the period when investment takes place. Equally, we could allow for depreciation. These extensions would complicate the algebra without affecting the substantive insights in this two-period setting.

⁶This parallels the standard informational assumption made in the optimal income tax literature. The restriction to linear income taxes is not important, because in our framework (without labor-leisure or savings choices, taxes do not distort private actions.

he/she avoids taxation. This implies that the tax rates in period s must satisfy $t_s^J \leq \tau_s$ (see Appendix). As with legal capacity, these non-taxable fractions are determined by investments. Here, what we have in mind is the build-up of institutions such as an administration (like the IRS) for the collection of income taxes, a system for the monitoring of tax compliance, etc.⁷

Let τ_1 be the initial (i.e., period 1) stock of "fiscal capacity" (a higher τ raises the feasible tax rate). As legal capacity, fiscal capacity does not depreciate but can be augmented by nonnegative investment in period 1, which costs $F(\tau_2 - \tau_1)$. We assume $F(0) = F_\tau(0) = 0$. It is plausible to think that investments in fiscal capacity are cheaper in a modern society than in a less developed one.

Apart from the need to invest in legal and fiscal capacity and the possibility to redistribute across groups, there is an additional, public-goods motive for raising taxes. Public goods have a linear payoff, $\alpha_s G_s$, common to all individuals. We assume that α_s has a distribution of possible realizations, with c.d.f. H and p.d.f. h , on $[0, \bar{\alpha}]$ where $\bar{\alpha} > 1$. This shock is assumed to be *iid* over time. The realized value of α_s is known when taxes t_s^J are set in period s . But when investments in fiscal capacity take place in period 1, the future value, α_2 , is stochastic and the investing government knows only its distribution. A first-order stochastic dominating shift in this distribution represents greater perceived benefits of public goods, for example, due to a greater risk of war in future. In this interpretation, α_s represents the threat of war and G_s the level of defense. Another interpretation would be a broad "welfare-state program" that gives benefits in common to both groups.

Capital Market Equilibrium Individual choices are easy to characterize (see the Appendix for a formal treatment). They imply horizontal demands for borrowing up to the point $\sigma^J \beta^J p_s^J w^J$ by high-return members of group J , i.e., these individuals put up all their wealth as collateral and invest maximally. Conversely, individuals with low returns are happy to lend at any market rate $r_s \geq r_L$, implying a horizontal supply of lending up to the point $(1 - \sigma^J) \beta^J w^J$ by low-return individuals in group J .

⁷An interesting possibility is that the same institutions that facilitate market transactions – such as a well-functioning audit system – also facilitate the taxation of individuals or firms. In this paper, we abstract from such "administrative complementarities" and show that legal and fiscal capacity naturally become complements even in their absence.

We assume that the maximal supply of lending exceeds the maximal demand for borrowing. This will be the case if the number of high-return projects is relatively low. Then, in a competitive equilibrium, the interest rate will be r_L . If we make the "natural" assumption that lenders in each group invest the same portion, l_s , of their wealth, we can write the market-clearing condition as:

$$\sigma^A \beta^A p_s^A w^A + \sigma^B \beta^B p_s^B w^B = l_s [((1 - \sigma^A) \beta^A w^A + (1 - \sigma^B) \beta^B w^B)]. \quad (1)$$

Indirect Utilities Putting these components together yields indirect utility functions for individuals in group J depending on whether they have access to a low or high return project:

$$v_{H,s}^J(t_s^J, p_s^J, G_s) = \alpha_s G_s + (1 - t_s^J)(r_H + p_s^J(r_H - r_L))w^J \quad (2)$$

and

$$v_{L,s}^J(t_s^J, p_s^J, G_s) = \alpha_s G_s + (1 - t_s^J)r_L w^J. \quad (3)$$

Tax Bases and Government Budget Constraints As a preliminary, define per capita net output in each group:

$$Y(p_s^J, \sigma^J, w^J) = [\sigma^J(1 + p_s^J)(r_H - r_L) + r_L]w^J. \quad (4)$$

Notice that the $Y(\cdot)$ function is increasing in p_s^J , because more property rights protection for group J allows for more financial intermediation which raises net output. It is also increasing in w^J and σ^J since richer individuals can afford larger projects, and surpluses are generated only by agents with high returns. Moreover, the gain from property rights protection, $Y_p(p, \sigma^J, w^J) = (r_H - r_L)\sigma^J w^J$, is increasing in wealth and the share of high-return agents, $Y_{pw}, Y_{p\sigma} > 0$, as both make efficiency gains more important. We will occasionally use the shorthand notation $Y_s = \beta^A Y(p_s^A, \sigma^A, w^A) + \beta^B Y(p_s^B, \sigma^B, w^B)$ to denote national income in period s .

In this notation, we can write (average) indirect utility for group J as

$$v_s^J = \alpha_s G_s + (1 - t_s^J) Y(p_s^J, \sigma^J, w^J). \quad (5)$$

The government budget constraints are

$$\sum_J t_1^J \beta^J Y(p_1^J, \sigma^J, w^J) = G_1 + [L(\pi_2 - \pi_1) + F(\tau_2 - \tau_1)] \quad (6)$$

in period 1, and

$$\sum_J t_2^J \beta^J Y(p_2^J, \sigma^J, w^J) = G_2 \quad (7)$$

in period 2 (when there are no investments).

Political Regimes We represent political regimes in a simple reduced-form way, allowing for self-interested governments and political turnover. Thus, in each period, power is held by a government, which (over)represents group A or group B . We parametrize government preferences by the weights they attach to the utility of each group. Formally, let $\phi_J^J \geq \beta^J$ denote the weight that group J gives to itself when holding political power, and $\phi_J^K \leq \beta^K$ the weight group J gives to group $K \neq J$. We normalize so that $\phi_J^J + \phi_J^K = 1$. It is most convenient to work with an “overweighting” parameter $\rho = \phi/\beta$. For ease of exposition, we deal with a symmetric case where:

$$\bar{\rho} = \frac{\phi_A^A}{\beta^A} = \frac{\phi_B^B}{\beta^B} \geq \underline{\rho} = \frac{\phi_A^B}{\beta^B} = \frac{\phi_B^A}{\beta^A}.$$

Each group thus attaches the same relative weight to its own group.⁸

While quite specific, this way of modeling politics has the advantage of nesting the utilitarian social planning outcome as a special case. Specifically, $\bar{\rho} = \underline{\rho} = 1$ (i.e., $\phi_J^J = \beta^J$ and $\phi_J^K = \beta^K$) represents the weights that would be used by a utilitarian social planner. We shall compare the politically determined policies to the utilitarian benchmark as we proceed.

We use the binary indicator $\gamma_s \in \{A, B\}$ to denote the type of government in period s , and the parameter $\gamma^J \in [0, 1]$ to denote the (exogenously given) probability that the policy maker is of type J in each period.

While it would be preferable to develop a structural model of politics – something that we leave for future work – the parameters $(\bar{\rho} - \underline{\rho})$ and γ^J can still be given plausible institutional interpretations. We will interpret a smaller difference $(\bar{\rho} - \underline{\rho})$ as a more representative political system, such as a more democratic regime.⁹ Moreover, among democracies it is common to argue (see Section 4 below) that parliamentary rather than presidential systems of government, and proportional rather than majoritarian systems

⁸This is more than a normalization. However, it conveniently allows us to avoid indexing $\bar{\rho}$ and $\underline{\rho}$ by K and J .

⁹An alternative interpretation of $(\bar{\rho} - \underline{\rho})$ would be a more polarized society, due to greater ethnic or linguistic fractionalization.

of elections, generate more consensual political outcomes. Such consensus can be thought of as a smaller gap $(\bar{\rho} - \underline{\rho})$ between the welfare weights of the groups in and out of power. We will think of greater political stability, whatever the representativeness of the system, as a higher value of γ^J when group J holds power in period 1.

Timing In each period, s , the economy starts out with some given fiscal and legal capacity, $\{\pi_s, \tau_s\}$. The subsequent timing is as follows:

1. Nature determines which private agents have high and low-return investment opportunities, the value of public goods (military threat), α_s and which group enjoys political control, γ_s .
2. The government picks a policy vector comprising taxes, property-rights protection levels, and government spending $\{t_s^A, t_s^B, p_s^A, p_s^B, G_s\}$, and (in period 1 only) carries out investments in legal and fiscal capacity $\{\pi_2 - \pi_1, \tau_2 - \tau_1\}$ subject to the government budget constraint and anticipating equilibrium private sector responses.
3. Private agents pick their projects, the capital market clears, and agents consume.

As we have fully described private-sector behavior, we can now focus on government behavior.

3 Policy choices

We first study the choice of taxes, property-rights enforcement, and public spending in each period. Given the (linear) structure of our model, these choices can be studied separately from the investment decisions in period 1.

Let group J be in power and group K be out of power in period s . The objective function of the incumbent government is

$$\phi_J^J v_s^J + \phi_J^K v_s^K = \bar{\rho} \beta^J v_s^J + \underline{\rho} \beta^K v_s^K.$$

Using the preliminaries above, the policy vector $\{t_s^J, t_s^K, p_s^J, p_s^K, G\}$ chosen at stage 2 maximizes the objective:

$$\alpha_s G_s + \bar{\rho} (1 - t_s^J) \beta^J Y(p_s^J, \sigma^J, w^J) + \underline{\rho} (1 - t_s^K) \beta^K Y(p_s^K, \sigma^K, w^K), \quad (8)$$

for given α_s subject to the government budget constraint, (6) or (7), and the “institutional” constraints:

$$p_s^J \leq \pi_s, p_s^K \leq \pi_s, t_s^J \leq \tau_s \text{ and } t_s^K \leq \tau_s .$$

Benchmark Utilitarian Optimum To provide a benchmark for the analysis, we begin with the special case $\bar{\rho} = \underline{\rho} = 1$, i.e., where the policy choices are made by a utilitarian social planner in period s . This will be interesting in part to see what aspects of normative analysis are also features of politically determined policy.¹⁰ Our results for this case are summarized in:

Proposition 1 *In the utilitarian case ($\bar{\rho} = \underline{\rho} = 1$), then policy is as follows: (a) For $s \in \{1, 2\}$ and any $\gamma_s \in \{A, B\}$, $\alpha_s \in [0, \bar{\alpha}]$, equilibrium property rights always fully utilize all legal capacity*

$$p_s^J = p_s^K = \pi_s .$$

(b) *If $\alpha_s \geq 1$, then taxable capacity on both groups is fully utilized,*

$$t_s^J = t_s^K = \tau_s ,$$

and public goods are provided as

$$G_1 = \tau_1 Y_1 - L(\pi_2 - \pi_1) - F(\tau_2 - \tau_1) \text{ and } G_2 = \tau_2 Y_2 .$$

(c) *If $\alpha_s < 1$, for all $J, K \in \{A, B\}$, $G_s = 0$, for $s \in \{1, 2\}$ and $t_2^J = t_2^K = 0$ with $t_1^J = t_1^K = \hat{t}_1$ where:*

$$\hat{t}_1 Y_1 = L(\pi_2 - \pi_1) + F(\tau_2 - \tau_1)$$

The result in part (a) that legal capacity is fully utilized rests on the straightforward observation that the indirect utility function in (8) is increasing in both p_s^J and p_s^K . Intuitively, better property-rights enforcement raises the availability of public and/or private goods, for any given tax vector (t_s^A, t_s^B) . That legal capacity is always fully utilized ex post is essentially an application, in this context, of the famous Diamond and Mirrlees (1971) production efficiency result.

¹⁰ Acemoglu, Golosov and Tsyvinski (2007) pursue the same kind of issues in a different context.

Optimal taxation *cum* public goods provision depends on the realization of α_s . Part (b) shows that when $\alpha_s \geq 1$, individuals in both groups are taxed up to available fiscal capacity and tax revenue is used solely to finance public goods, except that the period 1 government also needs to pay for investments in state capacity (which implies less public goods provision). To prove this result, notice that when $\bar{\rho} = \underline{\rho} = 1$ a change in the tax rates of groups J and K to finance higher spending on public goods, by the government budget constraint, change the objective (8) by $(\alpha_s - 1)\beta^J Y(p_s^J, \sigma^J, w^J) dt_s^J$ and $(\alpha_s - 1)\beta^K Y(p_s^K, \sigma^K, w^K) dt_s^K$, respectively. Since the derivatives are constant, a corner solution is optimal. Intuitively, in a "war-time" economy the social value of public goods (α_s) is higher than the social value of private goods (1).

When the social value of public goods is lower than that of private goods, no public goods are provided by reversal of the same argument. Further, part (c) prescribes zero tax rates in period two while, in period one, taxes are levied solely to fund investments in state capacity. The government budget constraint shows that a decrease in t_s^J financed by an increase in t_s^K affects the objective (8) by $[(\beta^J Y(p_s^J, \sigma^J, w^J) \frac{\beta^K Y(p_s^K, \sigma^K, w^K)}{\beta^J Y(p_s^J, \sigma^J, w^J)} - \beta^K Y(p_s^K, \sigma^K, w^K))] dt_s^K = 0$. Intuitively, since the two groups have the same constant marginal utility of income (namely 1), a utilitarian planner gains nothing from redistributing across groups. Without loss of generality, we can assume that both groups face the same tax rate.

We now turn to optimal policy when policy choices are politically determined. For this case, we have the following:

Proposition 2 *With political control ($\bar{\rho} > 1 > \underline{\rho}$), then policy is as follows:*
(a) *For $s \in \{1, 2\}$ and any $\gamma_s \in \{A, B\}$, $\alpha_s \in [0, \bar{\alpha}]$, equilibrium property rights always fully utilize all legal capacity*

$$p_s^J = p_s^K = \pi_s.$$

(b) *If $\alpha_s \geq \bar{\rho}$, then taxable capacity on both groups is fully utilized,*

$$t_s^J = t_s^K = \tau_s,$$

and public goods are provided as

$$G_1 = \tau_1 Y_1 - L(\pi_2 - \pi_1) + F(\tau_2 - \tau_1) \quad \text{and} \quad G_2 = \tau_2 Y_2.$$

(c) If $\alpha_s < \bar{\rho}$, for all $J, K \in \{A, B\}$, public goods provision is set equal to zero, i.e., $G_s = 0$ for $s \in \{0, 1\}$, the first-period tax on the ruling group is

$$t_1^J = \frac{[L(\pi_2 - \pi_1) + F(\tau_2 - \tau_1)] - \tau_1 \beta^K Y(\pi_1, \sigma^K, w^K)}{\beta^J Y(\pi_1, \sigma^J, w^J)},$$

while the second-period tax on the ruling group is:

$$t_2^J = -\frac{\tau_2 \beta^K Y(\pi_2, \sigma^K, w^K)}{\beta^J Y(\pi_2, \sigma^J, w^J)}.$$

By part (a) a politically motivated government chooses the same property-rights protection as a utilitarian planner. The logic is similar: choosing less than full property-rights protection would mean throwing away resources which could be taxed to provide public goods or redistributive transfers (see below).¹¹ As will be clear in Section 4, however, the efficient use of legal capacity in each period certainly *does not* imply that every society will have high levels of property-rights protection, as these depend directly on investments in legal capacity.

Part (b) is a close cousin to the result in **Proposition 1 (b)** and the formal argument uses the same steps. The important difference is that a government representing group J compares the value of public goods with the value of transfers to its own group, which are worth $\bar{\rho} > 1$. As a result of this, public goods are provided in fewer states of the world (or no states at all, if $\bar{\rho} < \bar{\alpha}$).

In the redistributive states of the world, $\alpha_s < \bar{\rho}$, the difference with the utilitarian benchmark is more stark.¹² To derive this result in part (c)

¹¹Besley and Persson (2007, Section 5.3) develops an example when the production-efficiency result fails to hold. It extends the basic framework studied here with a labor market, which generates untaxed quasi-rents. If political institutions are non-inclusive and fiscal capacity is low the government representing group J may then have incentives to exclude group K from the full utilization of available legal capacity, so as to preserve high rents due to a supply of cheap labor for group J 's investment projects. But when fiscal capacity is above a certain level, the incentive to boost quasi-rents goes away. This is a further application of Diamond and Mirrlees (1971)'s insights: when powers to tax are sufficient, it is always optimal for the ruling group to maximize national income and use the tax system to redistribute it.

¹²One clean, although somewhat unrealistic feature, of the model is a dramatic change in policy even if $\bar{\rho}$ is only slightly below one. A model with some curvature in the utility function would yield a more continuous deviation from the utilitarian benchmark.

formally, substitute the government budget constraints into the objective (8) and take the derivative with respect to each tax rate. Because the resulting derivatives are constant, it is optimal to choose the corner solutions described in part (c). The result makes intuitive sense. As the ruling group overvalues its own welfare and \$1 worth of public goods is less valuable than \$1 of private income when $\alpha_s < \bar{\rho}$, it finds it optimal to provide no public goods and set a maximal tax on the non-ruling group to finance a transfer to itself. In period 1, this transfer is smaller to the extent that public revenues are set aside for financing improvements in state capacity. Note, that fiscal capacity is *less* than fully utilized in this case.¹³

Together, **Propositions 1** and **2** reveal exactly how political control with $\bar{\rho} > \underline{\rho}$ distorts policy outcomes, compared to a utilitarian outcome. Political control implies a *taxation distortion*: in redistributive states of the world, one group always pays maximal taxes to fund redistribution, whereas the utilitarian criterion does not favor such redistribution. It also implies a *public goods distortion*: common-interest states of the world are too few, as public goods are not provided, even though they are socially valuable by the utilitarian criterion, if $\alpha_s \geq 1$. From an *ex ante* perspective, public goods are *not* provided with probability $H(\bar{\rho})$ compared to $H(1)$ in the utilitarian case. The size of the public goods distortion depends on the inclusiveness of political institutions. If $\bar{\rho}$ is very large, or public goods not very valuable (war is unlikely) so the distribution of α is skewed to the left, we will observe mainly a redistributive rather than a common interest state.

4 Investments in State Capacity

Having established the structure of optimal policy, the next task is to study investments in legal and fiscal capacity in period 1.

4.1 Optimal Investment Decisions

To characterize these investments, we need some preliminaries and notation. Assume that group J holds power in period 1. At this point, the governing

¹³We are assuming that fiscal capacity does not affect the size of the income transfer that can be made to group J (other than through its effects on the maximal taxes that can be raised from group K).

group faces uncertainty over the period 2 realization of α as well as government identity. Drawing on the results in **Propositions 1-2** and going through some algebra, the Appendix shows that we can write the expected payoff to group J as a function of the two forms of state capacity:

$$\begin{aligned} W^J(\tau_2, \pi_2) = & (1 - \tau_2)[\bar{\rho}\beta^J Y(\pi_2, \sigma^J, w^J) + \underline{\rho}\beta^K Y(\pi_2, \sigma^K, w^K)] \\ & + \tau_2\{([1 - H(\bar{\rho})] E(\alpha_2|\alpha_2 \geq \bar{\rho}) \\ & + H(\bar{\rho})[\gamma^J \bar{\rho} + (1 - \gamma^J) \underline{\rho}])[\beta^J Y(\pi_2, \sigma^J, w^J) + \beta^K Y(\pi_2, \sigma^K, w^K)]\} . \end{aligned} \quad (9)$$

We can then state the optimal investment decision in state capacity, as the maximization of:

$$W^J(\tau_2, \pi_2) - \lambda(\alpha_1)[L(\tau_2 - \tau_1) + F(\tau_2 - \tau_1)] ,$$

where $\lambda(\alpha_1) = \max\{\alpha_1, \bar{\rho}\}$ is the *realized* (marginal) cost of public funds in period 1. To help characterize the solution, we define two more parameters. The first is the net *expected* (marginal) value of *public* funds in period 2 for group J

$$\lambda_2^J = [1 - H(\bar{\rho})] E(\alpha_2|\alpha_2 \geq \bar{\rho}) + H(\bar{\rho})[(\gamma^J - \omega^J)(\bar{\rho} - \underline{\rho})] , \quad (10)$$

where $\omega^J = \frac{\sigma^J w^J \beta^J}{\Omega}$, $\omega^K = \frac{\sigma^K w^K \beta^K}{\Omega}$ are the shares of the two groups in total pledgeable wealth held by agents with high-return projects, $\Omega = [\sigma^A w^A \beta^A + \sigma^B w^B \beta^B]$, and where we have used the adding-up constraints $\gamma^J + \gamma^K = 1$ and $\omega^J + \omega^K = 1$. Note that ω^J and ω^K reflect each group's economic power, in terms of investment opportunities. The first term in λ_2^J reflects the expected value of public goods in common interest-states of the world, whereas the second reflects the expected value of transfers to J less expected taxes paid by J in redistributive states of the world. We also define the net *expected* (marginal) value of *private* funds to high-return for group J agents in period as:

$$\rho^J = \underline{\rho} + \omega^J(\bar{\rho} - \underline{\rho}) . \quad (11)$$

This is an average of $\bar{\rho}$ and $\underline{\rho}$ with weights reflecting the share of the wealth of the high-return investment agents in group J .

Assuming that there exists sufficient inherited fiscal capacity to fund investments at the desired level, the first-order conditions for investing in state capacity can be written as:

$$\begin{aligned} (\rho^J + \tau_2 \lambda_2^J)(r_H - r_L)\Omega & \leq \lambda(\alpha_1) L_\pi(\pi_2 - \pi_1) \\ \text{c.s. } \pi_2 - \pi_1 & \geq 0 \end{aligned} \quad (12)$$

and

$$\lambda_2^J \left[(1 + \pi_2) (r_H - r_L) \Omega + r_L (\beta^J w^J + \beta^K w^K) \right] \leq \lambda (\alpha_1) F_\tau (\tau_2 - \tau_1) \quad (13)$$

$$\text{c.s. } \tau_2 - \tau_1 \geq 0 .$$

Conditions (12) and (13) summarize all the forces that shape investment in state capacity.

Before exploring in detail the implications of (12) and (13) for observable outcomes, we state a basic result:

Proposition 3 (a) *In the utilitarian case ($\bar{\rho} = \underline{\rho} = 1$), there is always investment in both types of state capacity.*

(b) *With political control ($\bar{\rho} > 1 > \underline{\rho}$), a necessary and sufficient condition for both groups to invest in both types of state capacity is*

$$\lambda_2^J > 0, \text{ for } J = A, B.$$

If this condition does not hold, then at most one group invests in fiscal capacity.

Clearly, if $\lambda_2^J > 0$, the left-hand sides of both (13) and (12) are positive and group J values improvements in both kinds of state capacity. In the utilitarian case, this is always the case: λ_2^J defined in (10) has a positive first term because public goods are always provided in some states (because $\bar{\alpha} > 1$), while the second term in (10) is zero because a utilitarian decision maker has no intrinsic demand for redistribution.

With political control, the sign of λ_2^J is no longer certain. But we can find alternative sufficient conditions for positive investments. One is that public goods are valuable enough, so the first term in λ_2^J is large enough to outweigh any negative second term due to expected redistribution away from group J . Another is that political stability is high enough, so that $\gamma^J - \omega^J > 0$ making the second term always positive, guaranteeing expected redistributive benefits in addition to any benefits from public goods. More generally, if economic power and political power are broadly in line with one another, i.e., $\gamma^J \approx \omega^J$, then we are likely to have $\lambda_2^J > 0$.

However, there are parameter values for which neither group has any incentive to invest in fiscal capacity. Assume that the political regime is very unrepresentative, such that $\bar{\rho} > \bar{\alpha} > 1$ and public goods are not provided in any state of the world. If the political regime is also very unstable such that

$\gamma^J < \omega^J$, $J = A, B$, both groups fear to be expropriated often enough that $\lambda_2^J < 0$. Then, none of them invests at all in fiscal capacity, although one or both may still invest in legal capacity. In this case, the political outcome leads to underinvestment in the state compared to the utilitarian benchmark. In welfare terms, the state is investing too little in fiscal capacity and then using that capacity for redistribution rather than public goods provision.

If $\lambda_2^J > 0$ holds for both groups $J \in \{A, B\}$, the left-hand side of (12) is increasing in τ_2 and the left-hand side of (13) is increasing in π_2 . Then, investments in legal and fiscal capacity are *complements*. As a result, the demand for fiscal capacity – to finance redistribution or public goods – is greater when the economy is more productive, as a given increment of taxation raises more revenues due to a larger tax base. Equally, having larger fiscal capacity gives an extra boost to the demand for legal capacity to support markets, because it gives additional public funds that can be used productively. This complementarity is of genuine economic interest and corresponds to a situation in which common interests in state development are important.

From now on, we therefore focus on the case where $\lambda_2^J > 0$ for both groups. This will be true as long as there are sufficient common interests, i.e. the probability that α_2 is greater than $\bar{\rho}$ is large enough.

Finally, note that if $\lambda_2^J > 0$, we may have overinvestment as well as underinvestment in state capacity relative to the utilitarian benchmark. From (12) and (13) and supermodularity – see below – a sufficient condition for overinvestment is that both λ_2^J and ρ^J are increasing in $\bar{\rho}$ evaluated at $\bar{\rho} = 1$. Taking the derivatives of λ_2^J and ρ^J and imposing the constraint $\beta^J \bar{\rho} + (1 - \beta^J) \underline{\rho} = 1$, we obtain the following two conditions: $\partial \lambda_2^J / \partial \bar{\rho} = H(1) (\gamma^J - \omega^J) - h(1) (1 - \beta^J) > 0$ and $\partial \rho^J / \partial \bar{\rho} = (\omega^J - \beta^J) / (1 - \beta^J) > 0$. Roughly speaking, overinvestment emerges with group J in power when the expected gains from redistribution to the group are large enough to outweigh the expected losses from less public goods provision (the condition on $\partial \lambda_2^J / \partial \bar{\rho}$) and, at the same time, the group's share in productive wealth is no smaller than its population share (the condition on $\partial \rho^J / \partial \bar{\rho}$).

4.2 Determinants of State Capacity

What does the model say about the various determinants of investment in state capacity? In a first step, we prove a set of results (in **Propositions 4-7**) that hold under very general conditions and regardless of which group is in power. This is because, with complementarity between investments, the

payoff functions are supermodular and we can exploit results on monotone comparative statics: any factor that raises the value of the left hand side of both (12) or (13) will raise investments in both forms of state capacity.¹⁴ More formally, suppose that we write an objective function in “reduced form” as $f(\tau_2, \pi_2; m)$ for relevant “parameters” m and suppose that $f(\cdot)$ is supermodular in (τ_2, π_2) . Then (τ_2, π_2) is monotonically increasing in m if $\partial^2 f(\cdot) / \partial \tau_2 \partial m \geq 0$ and $\partial^2 f(\cdot) / \partial \pi_2 \partial m \geq 0$. This is exactly the condition that a change in a certain parameter raises the left hand side of both (12) and (13).

In a second step (**Proposition 8**), we derive a more specific results on how the distribution of economic power (wealth) affects institution building. This requires some additional regularity conditions.

We start with findings about wealth and the gains from trade:

Proposition 4 *Countries with higher wealth, as measured by Ω , optimally choose larger state capacity of both kinds. Larger gains from trade in markets, as measured by higher σ^A, σ^B , or $(r_H - r_L)$, also raise investment in both fiscal and legal capacity.*

This proposition says that richer countries will choose to have greater state capacity. Indeed, the marginal benefit to investing in fiscal capacity is given by the size of national income, the term $(1 + \pi_2)(r_H - r_L)\Omega + r_L(\beta^J w^J + \beta^K w^K)$ in (13) is equal to Y_2 . And, the marginal benefit of investing in legal capacity is proportional to the marginal benefit of better property rights, the term $(r_H - r_L)\Omega$ in (12). Note that **Proposition 4** applies, even if higher wealth or better trading opportunities accrue exclusively to the group that is not in power. This is because taxes finance public goods and this creates a common interest in investing even if $\underline{\rho} = 0$.

The results in **Proposition 4** are consistent with the observation in Figure 1 that taxation and financial development are positively correlated with income both across and within countries. However, the causation runs from income to markets rather than the other way round.

The results are also consistent with the argument by Rajan and Zingales (2003) that financial development is positively correlated with openness to international trade, because the latter expands the returns to reallocating capital. These authors present historical evidence that financial development

¹⁴See Theorems 5 and 6 in Milgrom and Shannon (1994). This result is originally due to Topkis – and has been generalized in Milgrom and Shannon (1994) Theorem 4.

and openness have co-varied, both being high in the period before World War I, low in the interwar period and immediately after World War II, and then higher again in the last 30-40 years.¹⁵ We return to the relationship between financial development and income (growth) in Section 4.3 below.

We next explore how demand for public goods affects the incentive to invest.

Proposition 5 *A higher expected demand for public goods, a first order stochastically dominating shift in α , raises λ_2^J and thereby investment in state capacity. Investments in fiscal and legal capacity are decreasing in $\lambda(\alpha_1)$.*

The first result can be used to make sense of Tilly's (1990) hypothesis on the importance of war in building state capacity. However, it clearly applies more widely to any public goods that are national in character, such as broad health care programs or building a welfare-state. If the demand for such public goods or services is expected to be high, there is a large incentive to invest in state capacity as these are common-interest investments. But such investments have to be financed. This effect is represented in the parameter $\lambda(\alpha_1)$. When the period 1 demand for public goods is great, public funds are at a premium and investments lower. The greatest incentive to invest arises when $\lambda(\alpha_1) = \bar{\rho}$, i.e., when period 1 taxes are used for redistribution.

The next result concerns the impact of political turnover.

Proposition 6 *Greater political stability, represented by an increase in γ^J , increases λ_2^J and thereby investment in state capacity.*

To see this, observe that

$$\frac{\partial \lambda_2^J}{\partial \gamma^J} = H(\bar{\rho}) (\bar{\rho} - \underline{\rho}) \geq 0 \quad ,$$

i.e., a higher probability of group J remaining in power (lower turnover) raises the group's expected value of public funds in future. Intuitively, the risk is smaller that the investing group J will see group K use the state for redistributive purposes against group J 's interest in the future. This effect is also lower if $\bar{\rho} - \underline{\rho}$ is close to zero. As mentioned before, we can interpret

¹⁵Rajan and Zingales' informal theory emphasizes the rent-protection incentives of incumbents, which do not appear in our basic model. A similar point arises in Section 5.3 of Besley and Persson (2007).

this gap between the weights the political process places on the ruling group and the non-ruling group, as a less representative political system offering less minority protection.

The model thus suggests that an interesting “interaction” term should be found in the data – we should observe more developed economic institutions in politically stable countries, and this positive effect should be particularly large in less representative political systems with little protection of minorities. We know of no systematic empirical evidence on this issue.¹⁶

However, a good illustrative historical case study for how political stability can shape investment in state capacity in a non-democratic political system comes from England after the Glorious Revolution in 1688. This led to the political dominance of the Whigs in Parliament between 1715 and 1759 – see Stasavage (2007, Table 1). Mathias and O’Brien (1976) calculate that taxes as a share of GDP rose from 16% to 20% of GDP over this period. Moreover, the administrative institutions put in place during the same period meant that, after 1713, excises and indirect taxes levied on domestically produced goods and services accounted for more than three quarters of tax revenues (O’Brien, 2005). The considerable investment in state capacity by this dominant elite culminating in the introduction of an income tax, underpinned the fiscal superiority of the British over the French during the Napoleonic wars and assisted Britain to raise public debt credibly to fight those wars. In the years 1803 to 1812, the British government had accumulated sufficient fiscal capacity to raise taxes equal to a remarkable 36% of GDP (Mathias and O’Brien, 1976).

In addition to this interaction effect, we are interested in the direct effect of the representativeness of political regimes. To get at this, consider the effect of raising $\bar{\rho}$, subject to the constraint $\beta^J \bar{\rho} + (1 - \beta^J) \underline{\rho} = 1$. In general, this effect is quite complicated, interacting with the distribution of political power as represented by γ^J and economic power as represented by ω^J . We can neutralize these effects by supposing that $\beta^J = \omega^J = \gamma^J$. While the assumption $\gamma^J = \beta^J$ says that political power is allocated (probabilistically) in proportion to population size, $\beta^J = \omega^J$ implies that $\sigma^J w^J$ is the same in

¹⁶ Alesina, Baqir, and Easterly (1999) have emphasized how ethnically divided communities spend less on public goods. If we were to interpret $\bar{\rho} - \underline{\rho}$ as a measure of ethnic divisions, their finding would be predicted by our model, the probability of no public-goods provision is given by $H(\bar{\rho})$. But our model would have the additional prediction that such divisions interact with political instability to curtail investments in legal and fiscal capacity.

both groups, i.e., they have the same opportunities to invest. We then have:

Proposition 7 *If $\beta^J \approx \omega^J \approx \gamma^J$, a more representative political system, in the sense of a lower $\bar{\rho} - \underline{\rho}$, raises investment in both fiscal and legal capacity.*

To see this, observe that with $\beta^J = \omega^J = \gamma^J$ and the constraint $\beta^J \bar{\rho} + (1 - \beta^J) \underline{\rho} = 1$ then $\rho^J = 1$ and the second term in the expression for λ_2^J in (10) is zero so $\lambda_2^J = \int_{\bar{\rho}}^{\bar{\alpha}} \alpha_2 dH(\alpha)$, which is independent of J . The effect of an increase in $\bar{\rho}$ on ρ^J is therefore zero while the effect on λ_2^J is:

$$\frac{\partial \lambda_2^J}{\partial \bar{\rho}} = -h(\bar{\rho}) \bar{\rho} < 0.$$

So the marginal return to both fiscal and legal capacity increases for lower $\bar{\rho}$. By continuity, the result holds for small differences between β^J , ω^J , and γ^J .

Intuitively, more representativeness and minority protection lowers the value of redistribution and therefore public goods are supplied more often. As the state becomes more about common interests, the value of fiscal capacity increases and, by complementarity, so does the value of legal capacity. To see why this result requires the condition $\beta^J \approx \omega^J \approx \gamma^J$ suppose, for example, that the ruling group has $\gamma^J > \omega^J$. Then, a less representative political system can increase the value of future revenue λ_2^J since that group's political power (in an expected sense) is greater than its cost of taxation (proportional to ω^J).

A long tradition in political science, for example, Lijphart (1999) considers proportional electoral systems more consensual than majoritarian systems, while Persson, Roland and Tabellini (2000) argue that parliamentary democracies are more representative than presidential democracies. In these interpretations, **Proposition 7** predicts that we should see more investment in legal and fiscal capacity in such democracies, which appears consistent with the findings in Persson and Tabellini (2004) that parliamentary and proportional democracies have much higher government spending. The comparative static in **Proposition 7** also captures the idea that states with greater checks and balances are likely to have more state capacity. This parallels the argument of Schultz and Weingast (2003) who suggest that greater checks and balances in British political arrangements facilitated revenue raising. Sargent and Velde (1995) argue that France's desire to constrain the King's revenues resulting in an underdeveloped fiscal system played a central role in the economic events leading to the French revolution.

Finally, we would like to say something specific about the distribution of economic power and investments in state capacity. To do this, we simplify the model $\sigma^A = \sigma^B$. We then look at the effect of a higher share of wealth in the hands of group J , i.e., an increase in ω^J holding total wealth $(\beta^J w^J + \beta^K w^K)$ fixed. With a few additional regulatory conditions, we obtain:

Proposition 8 *Under Assumption 1 (see the Appendix), greater economic power of the ruling group, i.e., a higher value of ω^J , increases investment in legal capacity and reduces investment in fiscal capacity.*

Proof: see the Appendix.

The argument is straightforward. An increase in ω^J raises ρ^J but reduces λ_2^J , which – in turn – raises the marginal return to legal capacity but *reduces* the marginal return to fiscal capacity. **Assumption 1** essentially guarantees that the direct effects on the marginal returns to fiscal and legal capacity are not offset by indirect effects operating through the complementarity. The comparative statics then go in the expected direction, i.e., according to the change in the marginal benefits of the two types of state capacity.

Proposition 8 speaks to the wealth distribution between the groups in and out of power. It suggests that, *ceteris paribus*, a more unequal income distribution raises investments in legal capacity and cuts investments in fiscal capacity if the rich has a hold on political power, whereas the effects go the other way if the poor has political power. Because the effect of ω^J on ρ^J is larger, the higher is $\bar{\rho}$ this effect should be most pronounced in autocracies. In other words, the model predicts the protection of property rights to improve (deteriorate) and taxation to fall (rise) as income inequality becomes more pronounced in autocracies ruled by rich elites (poor masses).

Together, **Propositions 4-8** give a fairly complete understanding of the forces that shape the incentives to invest in state capacity.

4.3 Implications for Economic Growth

The simple structure of the model makes it easy to state the implications for economic growth, defined as the proportional increase in national income from period 1 to period 2. Using the earlier definition of per-capita income and the results in **Proposition 1**, a little algebra establishes:

$$\frac{Y_2 - Y_1}{Y_1} = \frac{(\pi_2 - \pi_1)(r_H - r_L)\Omega}{(1 + \pi_1)(r_H - r_L)\Omega + r_L \sum_J \beta^J w^J} .$$

Evidently, the growth rate is directly proportional to the investments in legal capacity. Since there is no private accumulation, higher growth comes about solely by better allocative efficiency facilitating gains from trade – achieving higher TFP. Thus, there are strong reasons to see a positive correlation between improvements of market-supporting economic institutions and income growth.

Legal capacity in our model is closely related to financial development: the amount of private credit is proportional to π . As noted in Section 2, many empirical studies have measured financial development precisely in this way and found it to be positively correlated with growth of GDP per capita. According to our model, financial deepening can indeed cause growth. But the relationship can easily go the other way. As we have seen in **Proposition 4**, higher income generally raises the incentives to invest in legal capacity leading to financial deepening.

In terms of fiscal institutions, taxation, and growth, the complementarity between fiscal and legal capacity delivers clear-cut results. If greater legal capacity is driven by any of the determinants emphasized in **Propositions 4-7**, we expect it go hand-in-hand with higher fiscal capacity. Variation in these forces would lead us to observe a *positive* correlation between higher taxes and faster growth. On the other hand, higher legal capacity driven by a more unequal income distribution, as in **Proposition 8**, could induce a negative correlation between fiscal capacity and growth. Finally, in the case when $\lambda_2^J < 0$ (so that there is no investment in fiscal capacity), legal capacity and national income are still positively correlated, while there is zero correlation between taxation and growth.

These theoretical findings are interesting in relation to some of the empirical findings in the macro literature on growth and development. Many researchers have found a positive correlation between measures of financial development, or property-rights protection, and economic growth (see for example, King and Levine, 1993 and Hall and Jones, 1999 and a number of subsequent papers). The discussion above cautions us that such correlations may indeed reflect a two-way relationship. On the other hand, those expecting to find a negative relation between taxes and growth have basically come up empty-handed (see for example, the overview in Benabou, 1997). Simple though it is, our model suggest a possible reason for these findings.

Our results are obtained in the absence of private capital accumulation. Persson and Besley (2007, Section 5.4) extends the same framework to include private investments. In that setting, building fiscal capacity has an

additional “standard” disincentive effect on growth because a higher value of τ_2 increases future expected taxes and lowers the marginal expected return to investing, thereby reducing capital accumulation. However, building legal capacity now has an additional positive effect on growth, because it raises the (gross) returns on private investment which stimulates private accumulation. As long as the complementarity between fiscal and legal capacity holds, the increases in both kinds of state capacity expand together with private incomes.

5 A Look at the Data

Our model predicts that fiscal systems and market-supporting legal institutions (particularly those fostering financial development) are jointly endogenous to a common set of economic, political and social variables. In this section, we take a preliminary look at data on measures of financial development, contract enforcement, and tax structure. We explore some conditional correlations between these outcome variables and the determinants suggested by our model, but do not make any claims of capturing causal relations.

Independent Variables As common determinants of the state capacity outcomes, we include three sets of independent variables. We hypothesize that the historical incidence of war serves as a proxy for the past demand for common public goods, G . Then, the model has the non-trivial implication that this proxy should be correlated with *both* forms of state capacity today. We use data from the Correlates of War data base to create a measure of how large a share of the years between 1816, or the year of independence (if later), and 1975 that a country was involved in an external military conflict.¹⁷

We also include some measures of political institutions. The theory predicts that the inclusiveness of political institutions is one of the key factors shaping investments in state capacity. As in the case of war, we should

¹⁷<http://www.correlatesofwar.org/>.

Specifically, we say that a country is at war in a specific year if either (or both) of the binary (0,1) variables *interstatewar* or *extrastatewar* – which both refer to external conflicts – is equal to unity. The mean of the resulting variable is 0.03 with a standard deviation of 0.73. The results in Tables 1 and 2 are robust to using different lags for this variable, including the average years of war up to 1900. The results also hold up if we use a dummy variable denoting whether a state has been involved in any external conflict before 1975, which guards against the influence of outliers such as France and Britain.

thus consider the incidence of inclusive institutions in the past. Accordingly, we measure the share of years from 1800 (or independence) to 1975 that a country was democratic (as defined by a strictly positive value of the *polity2* variable in the Polity IV data set).¹⁸ Given the discussion in Section 4 of differences across democratic institutions, we also measure the share of years the country was a parliamentary democracy.

Further, our specification for each outcome variable includes a set of indicators for legal origins, as in many recent studies of institutions following La Porta et al (1998). As mentioned above, our model suggests a theoretical role for legal origins via the cost function $L(\cdot)$. If some legal origins affect the ease with which contracting can be done, we would expect this to affect investments in legal capacity. Perhaps less trivially, we would also expect the same legal origins to affect investments in tax systems in the same direction through the basic complementarity between the two forms of state capacity.

Finally, we do *not* include income, income per capita, or other measures of development among the independent variables. According to our model, independent shocks to income can certainly affect investments in both forms of state capacity. But the analysis also clearly shows that state capacity helps determine income. Disentangling this two-way relation requires a more sophisticated empirical strategy than the one pursued here.

Legal Capacity Table 1 considers legal capacity, measured by financial development and contract enforcement, as the dependent variable. The first column reports results for a common measure of financial development in the literature beginning with King and Levine (1993), namely the private credit to GDP ratio.¹⁹ We take the average of this variable over all years from 1975 onwards. As all other outcome variables in Tables 1 and 2, this measure is scaled to lie between 0 and 1, with higher values indicating a greater level of state capacity. To rule out results driven by systematic differences across geography, we include a set of regional fixed effects (eight regions) in each regression. An increase in the proportion of years up to 1975 that a country has been in an external conflict is strongly positively correlated with this measure of financial development. Democracy does not seem to matter in a significant way. Interestingly, German and Scandinavian legal origins are positively correlated with private credit, but English and Socialist legal origin

¹⁸<http://www.cidcm.umd.edu/polity/>.

¹⁹We thank Giovanni Favara for providing us with these data.

are not (French legal origin is the excluded category).

Column (2) looks at the country's rank in terms of access to credit, using the indicators from the World Bank's *Doing Business* web site.²⁰ Again, our incidence-of-war variable is positively correlated with legal capacity. Parliamentary democracy is also significantly correlated with higher legal capacity according to this measure (the sum of the two democracy variables is significantly different from zero). As in column (1), German and Scandinavian legal origin are positively correlated with the outcome. Column (3) uses another variable from the *Doing Business* indicators, the country's rank in terms of investor protection.²¹ The findings are consistent with those in column (2).

Finally, we use a perceptions index of government anti-diversion policies from the International Country Risk Guide (ICRG), which itself is the sum of five different indexes, including contract enforcement and the rule of law. This index has been extensively used in the macro development literature (for example, Hall and Jones, 1999, Acemoglu, Johnson and Robinson, 2001), as a measure of the protection of property rights. We take the average of this index from the early 1980s to the late 1990s. Even though the source of this variable is quite different from the others, it tells the same story in terms of war experience, parliamentary democracy and German and Scandinavian legal origins. To summarize, the patterns in the data are consistent with the determinants of contract enforcement and financial development suggested by the model.²²

²⁰<http://www.doingbusiness.org/> The overall ranking is put together from four sub-components: (i) a Legal Rights Index, which measures the degree to which collateral and bankruptcy laws facilitate lending, (ii) a Credit Information Index, which measures rules affecting the scope, access, and quality of credit information, (iii) public credit registry coverage, and (iv) private credit bureau coverage. See Djankov, McLeish and Shelifer (2006) for further details.

²¹<http://www.doingbusiness.org/>

This ranking is assembled from four underlying indexes: (i) transparency of transactions (Extent of Disclosure Index) (ii) liability for self-dealing (Extent of Director Liability Index) (iii) shareholders' ability to sue officers and directors for misconduct (Ease of Shareholder Suit Index) (iv) strength of Investor Protection Index (the average of the three index). See Djankov, La Porta, Lopez-de-Silanes and Shleifer (2006) for details.

²²These findings are also consistent with wars directly stimulating financial systems through public debt issue. Of course, this is not inconsistent with our general argument and ideas. Indeed, a public debt channel would reinforce the general complementarities that we have identified. However, it is another channel for war to have an impact on financial development. That being said, introducing more public debt would not necessarily lead to better *private* contract enforcement and more *private* credit (in theory) except as an

Fiscal Capacity How does the fiscal capacity side of the story hold up? This aspect of state capacity is more difficult to measure in terms of observable outcomes, since the model predicts that fiscal capacity is not always fully utilized. What matters are the past investments that make it possible to raise taxes. Governments in countries with little fiscal capacity tend to use border taxes, such as tariffs, as the basis of their tax systems. They also tend to require less institutionalized structures of compliance compared to income taxation.

In Column (1) of Table 2, we use one minus the share of revenue from trade taxes as a first measure of fiscal capacity. This measure is based on IMF data and is expressed as an average from 1975 and onwards.²³ As predicted by the model, countries with a history of war are less reliant on trade taxes. German and Scandinavian legal origins are also correlated with greater fiscal capacity measured in this way. In column (2), we add in indirect taxation and find similar results, except that a high incidence of parliamentary democracy now also has the expected positive correlation.

In column (3), we gauge high fiscal capacity by an extensive income tax system, using the income tax to GDP ratio as our outcome measure. Again, we find past wars, past parliamentary democracy and German and Scandinavian legal origin to correlate with high fiscal capacity. Column (4) looks at overall taxes raised as a share of GDP. This outcome shows a similar pattern of correlations as the share of income taxes in GDP.

Summary Putting the results in Tables 1 and 2 together, the historical incidence of war, the historical incidence of parliamentary democracy, and German and Scandinavian legal origins are remarkably stable predictors of both legal and fiscal capacity. The correlations we have uncovered are in line with the predictions of our model, where both forms of state capacity have common origins in political institutions, the need to finance common interest public goods, and factors that shape the cost of investments. With the caveat made earlier, we also note that regressions of the same kind as those reported in Tables 1 and 2, but with income per capita as the dependent variable, produce very similar patterns of sign and significance.

unintended consequence of public sector financial development.

²³We thank Mick Keen for making the data on the structure of taxation used in Baunsgaard and Keen (2005) available to us. That paper documents the sources for the structure-of-taxation variables.

Even though the preliminary evidence is encouraging, much remains to do before we can claim to have identified causal effects in line with the predictions of the theory. There are many caveats. For example, in looking at the data over long time-periods, there may be a survivorship bias towards countries that appear in the data today. Related to this, one could also worry about whether there is reverse causation between state capacity and war. In future work, it may be fruitful to exploit evidence from the time-series experience of countries that have built legal and fiscal capacity to yield more convincing evidence, even if the set of countries with available data is more limited.

6 Concluding Comments

The historical experience of today's rich nations indicate that creation of state capacity to collect taxes and enforce contracts are key aspects of development. Equally, the current experience of today's poor nations indicate that state capacity cannot be taken for granted. We analyze investments in state capacity as purposeful decisions reflecting circumstance and institutional structure. Our theoretical analysis highlights the factors that shape these decisions and points to a basic complementarity between fiscal and legal capacity. The analysis brings together ideas from economic history, finance, development economics and political economics. A first inspection of the data suggests that the common determinants suggested by our theory do indeed correlate in the predicted way with various measures of legal capacity and fiscal capacity.

While we take a first step in modeling the forces that shape state capacity, further theoretical work is needed too. Studying the two-way relation between state capacity and development in the data should rely on theoretical predictions from a full-fledged dynamic model. A dynamic multi-period model would also permit the study of some issues bypassed here such as depreciation of state capacity, time- or income-dependent costs of capacity, and short-run vs. long-run determinants of accumulation. For example, we expect the complementarity between fiscal and legal capacity to lead to long-run overaccumulation of both types of capacity.²⁴

²⁴Besley and Persson (2007, Section 5.1) find such an overaccumulation result when they study a quasi steady state of a repeated model like the one in this paper, in which none of the groups has a further incentive to accumulate any form of state capacity.

Since the model uncovers clear links from political institutions to state capacity, it would be interesting to explore endogenous political change – especially the emergence of democracy – in our framework. Despite its broad scope, the paper deals only with one aspect of property rights, the market supporting role of property rights emphasized by, e.g., de Soto (2000). Other parallel issues concern the development of property rights against predation by the state as emphasized, for example, by North (1990). A more complete theory of state development would deal with both aspects of property rights and would understand the emergence of constraints on state capacity being abused.

External conflict is certainly an important source of common-interest public goods, but it is unsatisfying to treat every external conflicts as exogenous. Ideally, endogeneity of conflict should be explored in a model of multiple interdependent governments, who all have the option of investing in state capacity. In line with recent work in the democratic peace literature, such as de Mesquita et al, (1999), details of domestic institutions might then help determine the propensity to engage in foreign conflict.

Given the central role of common interests in state building in our model, it is also interesting to think of ways in which to make these interests endogenous. Many nations emphasize a sense of belonging that creates common interests and foster them explicitly through education and public programs. It would be interesting to introduce this as purposive behavior in the model.

Redistribution also plays an important role in our analysis. Internal conflicts such as civil wars reflect an extreme form of domestic redistributive conflict. Unlike external war, anticipated civil wars will therefore have detrimental effects on the incentive to build state capacity – see Besley and Persson (2008) who take the incidence of civil war as given. More generally, we expect building state capacity and the patterns of civil war and economic development to be jointly determined by initial historical conditions and basic economic and political factors. This is also an important topic for further research.

Even in the rudimentary form developed here, we believe that our analysis offers a new perspective on the institutional underpinnings of development. In particular, the state capacities that we analyze typically evolve quite slowly. This may help explain why historical patterns of prosperity are so highly persistent.

7 Appendix

Private Optimal Choices A member of group J can only borrow in period s by putting up a share, $c_s^J \leq 1$, of her wealth w^J as collateral. Denoting the amount borrowed by b_s^J , incentive compatibility implies (see further below):

$$b_s^J \leq p_s^J c_s^J w^J. \quad (14)$$

In addition to the notation in the text, let l_s denote the amount of lending provided by an individual, k_s the amount invested in a project, n_s the amount withheld from taxation in the informal sector, and let $d_s \in \{0, 1\}$ be a binary indicator for default on any amount borrowed. Since preferences are linear in private consumption (net income), we can write the utility of an individual in group J and period s as

$$v_s^J = \alpha_s G_s + (1 - t_s^J)(r_I k_s^J - r_s b_s^J + r_s l_s^J) + (t_s^J - \tau_s)n_s^J + r_s(b_s^J - p_s^J c_s^J w^J)d_s^J.$$

The second term on the right-hand side is the net after-tax return from projects cum capital markets transactions, the third is the return to concealing income from tax in the informal sector, and the fourth the net gain from defaulting on borrowing.

Consider an individual choosing $(k_s^J, b_s^J, n_s^J, c_s^J, d_s^J, l_s^J) \geq 0$, in period s subject to the wealth constraint, $k_s^J + l_s^J \leq w^J + b_s^J$, the collateral constraint, $c_s^J \leq 1$, and the tax avoidance constraint, $n_s^J \leq w^J$. It is immediate that any individual with an investment opportunity would find it optimal to borrow and invest a large amount, and then default on his debt, i.e., set $d_s^J = 1$, as long as $b_s^J > p_s^J c_s^J w^J$. This formally motivates the upper bound on borrowing in (14). Moreover, as long as taxes exceed the critical level $t_s^J > \tau_s$, it is optimal to set $n_s^J = w^J$, i.e., put all projects in the informal sector. This formally motivates the upper bound on the tax rate

Imposing the no-tax-arbitrage and no-default constraints, the optimal choices for individuals with different rates of return are simple to characterize. High-return individuals for whom $r_I \geq r_s$ find it optimal to put up all their wealth as collateral, $c_s^J = 1$, invest a maximum amount $k_s^J = (1 + p_s^J)w^J$, and borrow $p_s^J w^J$ to enjoy the surplus of their project. Individuals with low returns are happy to lend at any market rate $r_s \geq r_L$ that makes up for their opportunity cost of foregone return. Putting this logic together yields equations (2) and (3) in the text.

Derivation of the Investment Objective Exploiting **Propositions 1-3**, we can define in a straightforward way the payoffs to each group depending on whether it has control over policy in period 2. If group J controls policy, its utility is:

$$w_J^J(\alpha_2, \tau_2, \pi_2) = \bar{\rho}\beta^J Y(\pi_2, \sigma^J, w^J) + \underline{\rho}\beta^K Y(\pi_2, \sigma^K, w^K) + \quad (15)$$

$$\begin{cases} \tau_2[(\alpha_2 - \bar{\rho})\beta^J Y(\pi_2, \sigma^J, w^J) + (\alpha_2 - \underline{\rho})\beta^K Y(\pi_2, \sigma^K, w^K)] & \text{if } \alpha_2 \geq \bar{\rho} \\ \tau_2(\bar{\rho} - \underline{\rho})\beta^K Y(\pi_2, \sigma^K, w^K) & \text{if } \alpha_2 < \bar{\rho} . \end{cases}$$

Since this expression is increasing in both τ_2 and π_2 , the ruling group prefers access to greater taxable and legal capacity, other things equal. The corresponding payoff to group J when the other group K controls policy, calculated by applying group J 's own welfare weights, is as follows:

$$w_K^J(\alpha_2, \tau_2, \pi_2) = \bar{\rho}\beta^J Y(\pi_2, \sigma^J, w^J) + \underline{\rho}\beta^K Y(\pi_2, \sigma^K, w^K) + \quad (16)$$

$$\begin{cases} \tau_2[(\alpha_2 - \bar{\rho})\beta^J Y(\pi_2, \sigma^J, w^J) + (\alpha_2 - \underline{\rho})\beta^K Y(\pi_2, \sigma^K, w^K)] & \text{if } \alpha_2 \geq \bar{\rho} \\ \tau_2(\underline{\rho} - \bar{\rho})\beta^K Y(\pi_2, \sigma^K, w^K) & \text{if } \alpha_2 < \bar{\rho} . \end{cases}$$

These two expressions highlight a latent conflict of interest. When $\alpha_2 \geq \bar{\rho}$, no such conflict exists and the groups in power and out of power both want better state fiscal and legal capacity. When $\alpha_2 < \bar{\rho}$, instead, the group out of power is worse off when τ_2 is higher (cf. the negative term $(\underline{\rho} - \bar{\rho})$ in the last term of (16)), because taxes are used to redistribute income away from the non-ruling group towards the ruling group. While there is an obvious conflict of interest over fiscal capacity in this case, both groups continue to value improvements in legal capacity.

Let's assume that group J holds power in period 1. Define the expected payoff to this group with economic institutions (τ_2, π_2) :

$$W^J(\tau_2, \pi_2) = \gamma^J E\{w_J^J(\alpha_2, \tau_2, \pi_2)\} + (1 - \gamma^J) E\{w_K^J(\alpha_2, \tau_2, \pi_2)\} .$$

Using (15) and (16), it is straightforward to derive expected utility (over the realization of α) as a function of τ_2, π_2 to group J :

$$W^J(\tau_2, \pi_2) = (1 - \tau_2)[\bar{\rho}\beta^J Y(\pi_2, \sigma^J, w^J) + \underline{\rho}\beta^K Y(\pi_2, \sigma^K, w^K)]$$

$$+ \tau_2 \left\{ \begin{aligned} & [1 - H(\bar{\rho})] E(\alpha_2 | \alpha_2 \geq \bar{\rho}) + \\ & H(\bar{\rho}) [\gamma^J \bar{\rho} + (1 - \gamma^J) \underline{\rho}] [\beta^J Y(\pi_2, \sigma^J, w^J) + \beta^K Y(\pi_2, \sigma^K, w^K)] \end{aligned} \right\} .$$

Proof of Proposition 8 Let $\sigma^A = \sigma^B = \sigma$ and state:

Assumption 1: For all interior solutions for $(\tau_2 - \tau_1)$ and $(\pi_2 - \pi_1)$

$$\frac{F_{\tau\tau}}{F_\tau} > \frac{H(\bar{\rho})}{1-\tau_2 H(\bar{\rho})} \text{ and } \frac{L_{\pi\pi}}{L_\pi} > \frac{(r_H - r_L) \sigma \lambda_2^J (1 - \tau_2 H(\bar{\rho}))}{[(1 + \pi_2)(r_H - r_L) \sigma + r_L] (\rho^J + \tau_2 \lambda_2^J) H(\bar{\rho})} ,$$

which will hold provided that $F_{\tau\tau}/F_\tau$ and $L_{\pi\pi}/L_\pi$ are large enough. The Hessian to the system made up by (12) and (13) is:

$$\begin{bmatrix} -\lambda(\alpha_1) L_{\pi\pi} & (r_H - r_L) \Omega \lambda_2^J \\ (r_H - r_L) \Omega \lambda_2^J & -\lambda(\alpha_1) F_{\tau\tau} \end{bmatrix} .$$

For an optimum, the (Jacobian) determinant of this matrix has to be positive. Using the first-order conditions (12) and (13) to substitute out $-\lambda(\alpha_1)$, this requires:

$$\frac{F_{\tau\tau}}{F_\tau} \cdot \frac{L_{\pi\pi}}{L_\pi} - \frac{(r_H - r_L) \sigma \lambda_2^J}{[(1 + \pi_2)(r_H - r_L) \sigma + r_L] (\rho^J + \tau_2 \lambda_2^J)} > 0 ,$$

which is implied by **Assumption 1**. To derive the comparative statics, use Cramer's rule to obtain:

$$\frac{d((\pi_2 - \pi_1))}{dw^J} = \frac{\lambda(\alpha_1) F_{\tau\tau} (\bar{\rho} - \underline{\rho}) (r_H - r_L) \Omega (1 - \tau_2 H(\bar{\rho})) - \lambda_2^J (r_H - r_L) \Omega (\bar{\rho} - \underline{\rho}) H(\bar{\rho}) [(1 + \pi_2)(r_H - r_L) \Omega + r_L \frac{\Omega}{\sigma}]}{[\lambda(\alpha_1)]^2 L_{\pi\pi} F_{\tau\tau} - [(r_H - r_L) \Omega \lambda_2^J]^2} ,$$

an expression which, using (13), is positive if:

$$\frac{F_{\tau\tau}}{F_\tau} > \frac{H(\bar{\rho})}{1 - \tau_2 H(\bar{\rho})} ,$$

which is the first part of **Assumption 1**. In addition, we have:

$$\frac{d(\tau_2 - \tau_1)}{dw^J} = \frac{\lambda_2^J (r_H - r_L) \Omega (\bar{\rho} - \underline{\rho}) (r_H - r_L) \Omega (1 - \tau_2 H(\bar{\rho})) - \lambda(\alpha_1) L_{\pi\pi} (\bar{\rho} - \underline{\rho}) H(\bar{\rho}) [(1 + \pi_2)(r_H - r_L) \Omega + r_L \frac{\Omega}{\sigma}]}{[\lambda(\alpha_1)]^2 L_{\pi\pi} F_{\tau\tau} - [(r_H - r_L) \Omega]^2 (\lambda_2^J)^2} ,$$

which, using (12), is negative if:

$$\frac{L_{\pi\pi}}{L_\pi} > \frac{(r_H - r_L) \sigma \lambda_2^J (1 - \tau_2 H(\bar{\rho}))}{[(1 + \pi_2)(r_H - r_L) \sigma + r_L] (\rho^J + \tau_2 \lambda_2^J) H(\bar{\rho})} ,$$

which is the second part of **Assumption 1**. ■
